List of Laramide volcanic-shallow intrusive centers/detrital zircons shown in Figure 1

- 1 - 73 Ma for the diorite dike of Sleeping Ute Mountain, Colorado (Gonzales, 2015)
- 2 - 68 Ma for the granodiorite-diorite porphyry stock of Hermosa Peak, Colorado (Gonzales, 2015)
- 3 - 69–65 Ma for the granite-diorite porphyry sill of Coal Bank Pass, Colorado (Gonzales, 2015)
- 4 - 70 Ma for the diorite stock of La Plata Mountains ‘Notch’, Colorado (Gonzales, 2015)
- 5 - Cretaceous McDermott Formation with major 70 Ma detrital zircon age peak, Colorado (Pecha et al., 2018)
- 6 - Cretaceous Kirtland Formation with major 75 Ma detrital zircon age peak, New Mexico (Pecha et al., 2018)
- 7 - 75–73 Ma ash-fall tuffs of McRae Formation, Love Ranch Basin, New Mexico (Amato et al., 2017)
- 8 - ~75 Ma monzonite porphyry stock and dacite sill of Twin Peaks, Burro Mountains, New Mexico (Amato et al., 2017).
- 9 - 73–70 Ma ash-fall tuffs of Ringbone/Skunk Ranch and sandstone of the Cretaceous Ringbone Formation with major 73 Ma detrital zircon age peak, Little Hatchet Mts, New Mexico (Clinkscales and Lawton., 2015)
- 10 - 73 Ma andesite, southern Winchester Mountains, Arizona (Mizer, 2018)
- 11 - 76 Ma andesite of Bronco Volcanics and Uncle Sam Tuff, 75 Ma dacite porphyry and 73 Ma Schieffelin granodiorite, Tombstone mining district, Arizona (Mizer, 2018)
- 12 - 75 Ma Granite Peak stock, Whetstone Mountains, Arizona (Mizer, 2018)
- 13 - 75 Ma granodiorite, quartz diorite and felsic dikes, Cerro Colorado mining district, Arizona (Mizer, 2018)
- 14 - 75 Ma El Tiro granite and dacite porphyry, Silver Bell mining district, Arizona (Mizer, 2018)
- 15 - 74 Ma Williamson Canyon Volcanics, Banner mining district, Arizona (Mizer, 2018)
- 16 - 73 Ma Concentrator Volcanics, Ajo mining district, Arizona (Mizer, 2018)

Sample Preparation

Hand-sized samples of Pierre Shale and Trinidad Sandstone were crushed and pulverized to less than mm-sized pieces and washed to remove the finest clays. Based on observed sizes of heavy minerals in the crushed material, the sandstone was sieved into 63 – 125 μm and 20 – 63 μm fractions and shale into a 20 – 63 μm fraction. Detrital zircon and other heavy minerals were separated from the less dense minerals in each of the sieved fractions using Lithium Metatungstate (LMT) heavy liquid adjusted to a density of 2.9 g/cc. The heavy mineral separates were mounted randomly in 25 mm epoxy rounds, without pre-screening based on magnetic susceptibility, shape or color, which can bias detrital zircon age populations (Sircombe and

Stern, 2002; Sláma and Košler, 2012; Markwitz et al., 2017). In addition, the separates were mounted as monolayers so that polishing intersected the central portion of each grain, allowing meaningful comparisons of two-dimensional size measurements between different grains (Sylvester, 2012). Thus, the heavy mineral separates provided a grain mount for each of the coarse (TSC) and fine (TSF) heavy mineral fractions of the Trinidad Sandstone and another mount for the heavy mineral fraction of the Pierre Shale (PSM). As well, three thin sections (PSTS) were made from mudstone-rich layers in the Pierre Shale to date detrital zircons associated with the finest fraction of the rock and compare their morphologies and ages to detrital zircons extracted from the bulk sample by crushing.

SEM and LA-ICP-MS Analysis

Detrital zircon grains were located and identified in the mounts and sections using energy-dispersive X-ray spectroscopy (EDS) and backscattered electron (BSE) image analysis with automated scanning electron microscope (SEM) instruments: an FEI Mineral Liberation Analyzer (MLA) (Fandrich et al., 2007; Sylvester, 2012) for the grain mounts and a TESCAN Integrated Mineralogical Analyzer (TIMA) (Hrstka et al., 2018) for the thin sections. SEM metadata are given in Table DR1. Representative zircon BSE images are shown in Figure DR1.

U-Pb age analyses of zircon were made using a Nu Plasma AttoM magnetic sector inductively coupled plasma – mass spectrometry (ICP-MS) coupled to an ESI NWR193UC laser ablation (LA) system consisting of a TwoVol2 ablation chamber and a Coherent Excistar 193 nm ArF excimer laser. Detrital zircons were chosen for analysis in random fashion to avoid selection bias. Laser spots (20- and 12- μm wide for detrital zircons in mounts and thin sections, respectively) were placed on regions of zircon grains free of fractures, inclusions, or overgrowths, guided by BSE images. For grains approaching 20- μm in diameter, it was

sometimes a challenge to place the 12- μm spot without being close to the grain rim, or intersecting small fractures, both of which sometimes have more Pb loss or common Pb than fracture-free regions within grains. Also, for zircon grains analyzed directly in thin sections, care was taken not to overlap the laser beam on to the surrounding matrix, which was rich in common Pb in the case of the mudstones of this study. Careful imaging of the zircon grains in both transmitted and reflected light and measuring grain dimensions prior to laser ablation allowed the choice of laser spot size and positioning to be made most effectively.

Analytical details and instrument parameters are included in Table DR1. Zircon 91500 (Wiedenbeck et al., 2004) was used to correct for mass spectrometer bias on Pb/Pb and U/Pb isotopic ratios and downhole U/Pb isotopic fractionation (Košler et al., 2002) and calculate U and Th concentrations from count rates. Pb/Pb and U/Pb isotopic ages and U and Th concentrations were determined using Iolite software (v. 3.63) with the VizualAge DRS (Petrus and Kamber, 2012). Zircon ages were corrected for common Pb in Iolite using the Andersen (2002) method where the corrected fraction of common Pb >0.01 , except where the correction increased the % discordancy of the grain in the Wetherill Concordia diagram. U-Pb detrital zircon data for the Pierre Shale and Trinidad Sandstone samples are listed in Tables DR2 – DR5. Figure DR2 shows Wetherill Concordia diagrams for detrital zircons in the Pierre Shale and Trinidad Sandstone samples.

Zircon secondary reference materials (SRMs) were analyzed with the detrital zircons from Pierre and Trinidad samples as a check and monitor on data quality: Fish Canyon Tuff zircon ($^{206}\text{Pb}/^{238}\text{U} = 28.478 \pm 0.024$ (2s) Ma; Schmitz and Bowring, 2001); Plešovice zircon ($^{206}\text{Pb}/^{238}\text{U} = 337.16 \pm 0.11$ (2s) Ma; Sláma et al., 2008 recalculated by Horstwood et al., 2016); Temora-2 zircon ($^{206}\text{Pb}/^{238}\text{U} = 416.78 \pm 0.33$ (2s) Ma; Black et al., 2004); Oracle zircon

($^{207}\text{Pb}/^{206}\text{Pb} = 1437.05 \pm 0.77$ (2s) Ma; Arizona LaserChron Center website, laserchron.org); Tan Brown zircon ($^{207}\text{Pb}/^{206}\text{Pb} = 2512.24 \pm 0.71$ (2s) Ma; Bauer et al., 2020); Owens Gully Diorite (OG1) zircon ($^{207}\text{Pb}/^{206}\text{Pb} = 3465.4 \pm 0.6$ (2s) Ma; Stern et al., 2009). U-Pb zircon data for the SRMs analyzed with 20- and 12- μm spots are listed in Tables DR6 and DR7 respectively. Figures DR3 and DR4 show Wetherill Concordia diagrams for zircon SRMs analyzed with 20- and 12- μm spots respectively.

We note that the 12- μm spot sizes produce somewhat older ages (~ 2 Ma beyond analytical uncertainty) in Plešovice and Temora2 reference materials than the 20- μm spots and their accepted ages. The significance is likely the result of both (1) the presence of somewhat older age domains at small scales intersected more precisely by 12- μm than 20- μm laser ablation spots and (2) the smaller number of 12 μm vs 20 μm spot analyses (27 vs 123 for Plešovice, and 22 vs 83 for Temora2), which were insufficient to provide a representative sample both younger and old age domains and yield an overall average within uncertainty of the accepted age. SIMS analyses, which have spot sizes similar to the 12- μm laser spots used here, albeit with pit depths of only 1-2 μm , have identified older domains in both zircon reference materials previously. Sláma et al. (2008) reported that SIMS U-Pb analyses of Plešovice zircon yielded a weighted mean $^{206}\text{Pb}/^{238}\text{U}$ date of 341.4 ± 1.3 Ma (61 analyses from 33 individual grains). Figure 11 of Sláma et al. (2008) shows individual SIMS dates as old as 353.1 ± 2.5 Ma. Black et al. (2004) found a weighted mean $^{206}\text{Pb}/^{238}\text{U}$ SHRIMP date of 418.1 ± 2.2 Ma for Temora2, with 15 of the 51 analyses giving dates between 430 - 425 Ma. The main implication is that, as laser ablation spot sizes continue to decrease, small-scale heterogeneities in zircon grains will be recognized increasingly.

Figure S1. Representative backscattered electron (BSE) Images of detrital zircon in the two major age populations (ca. 71 and 1690 Ma) of the Pierre Shale and Trinidad Sandstone

Classification of Zircon Grain Morphology Types

Type 1 – Complete, euhedral grain cross sections with oscillatory zoning, suggesting early crystallization free from competing mineral growth

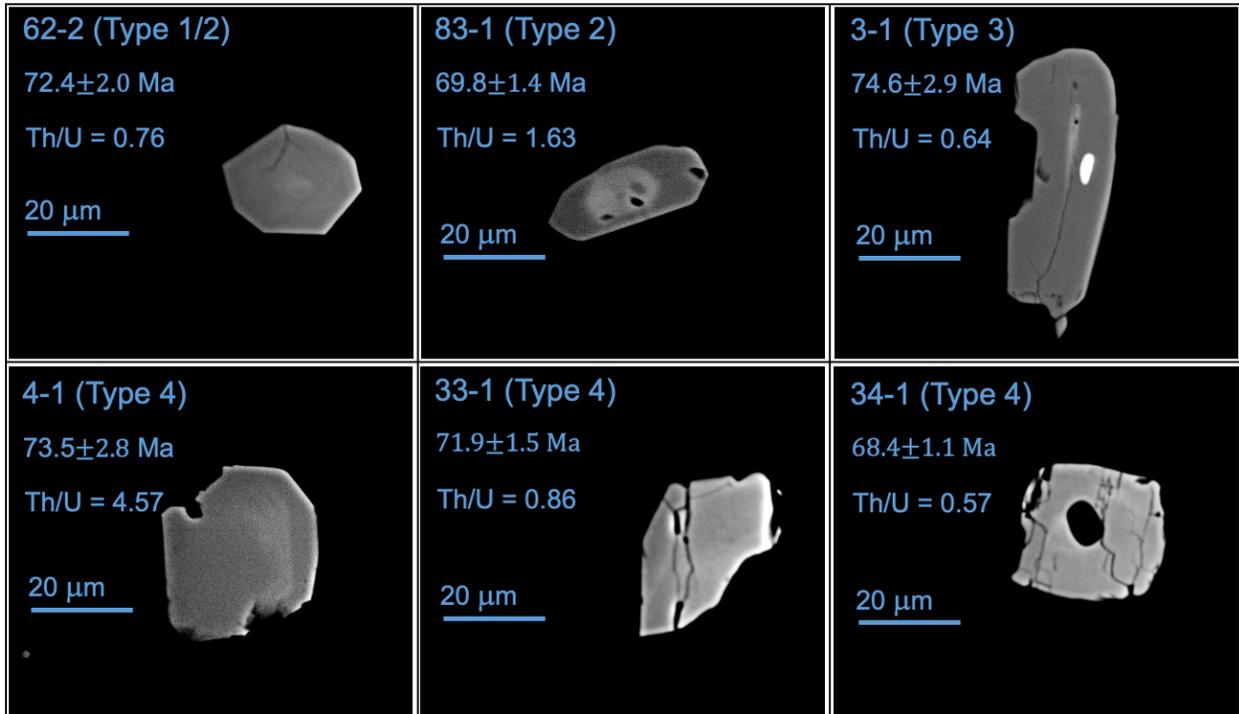

Type 2 – Complete or nearly complete, subhedral grain cross sections, often fractured, with diffuse oscillatory to patchy zoning

Type 3 – Grain cross sections with irregular, embayed crystal faces, suggesting late-stage crystallization interstitial to adjacent minerals in the crystalline source rock

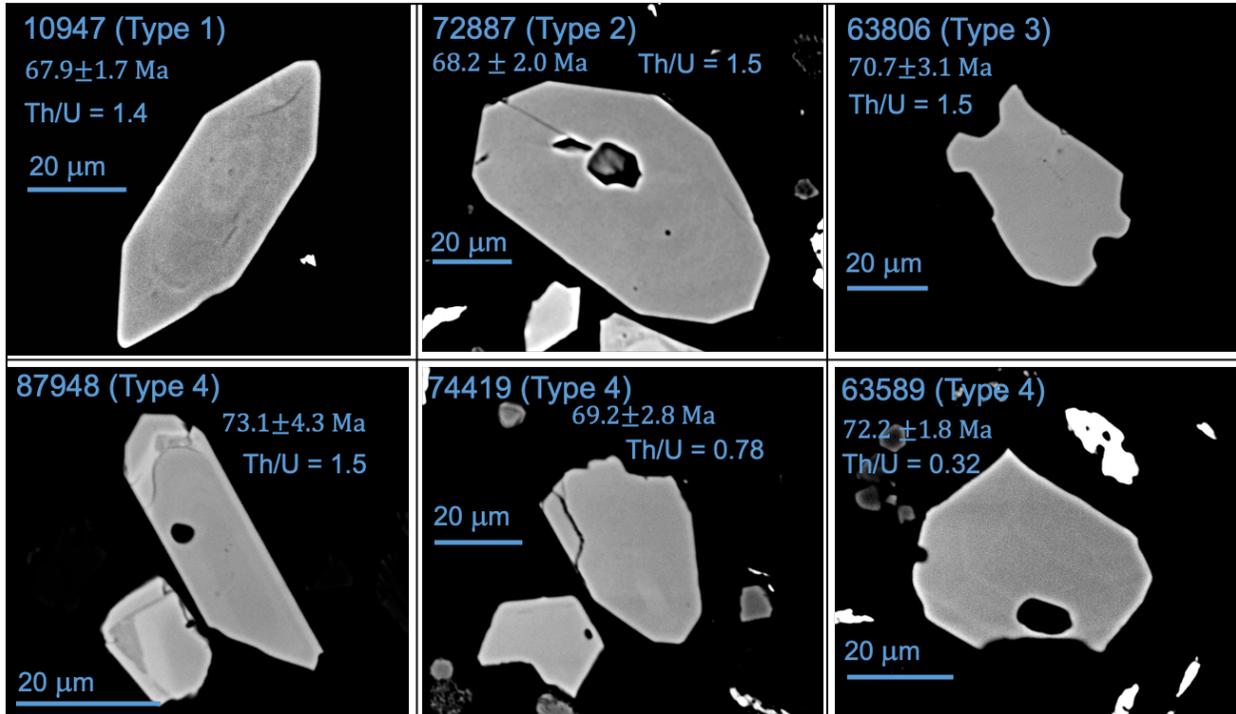

Type 4 – Crystal fragments

71 ± 3 Ma Zircon Population

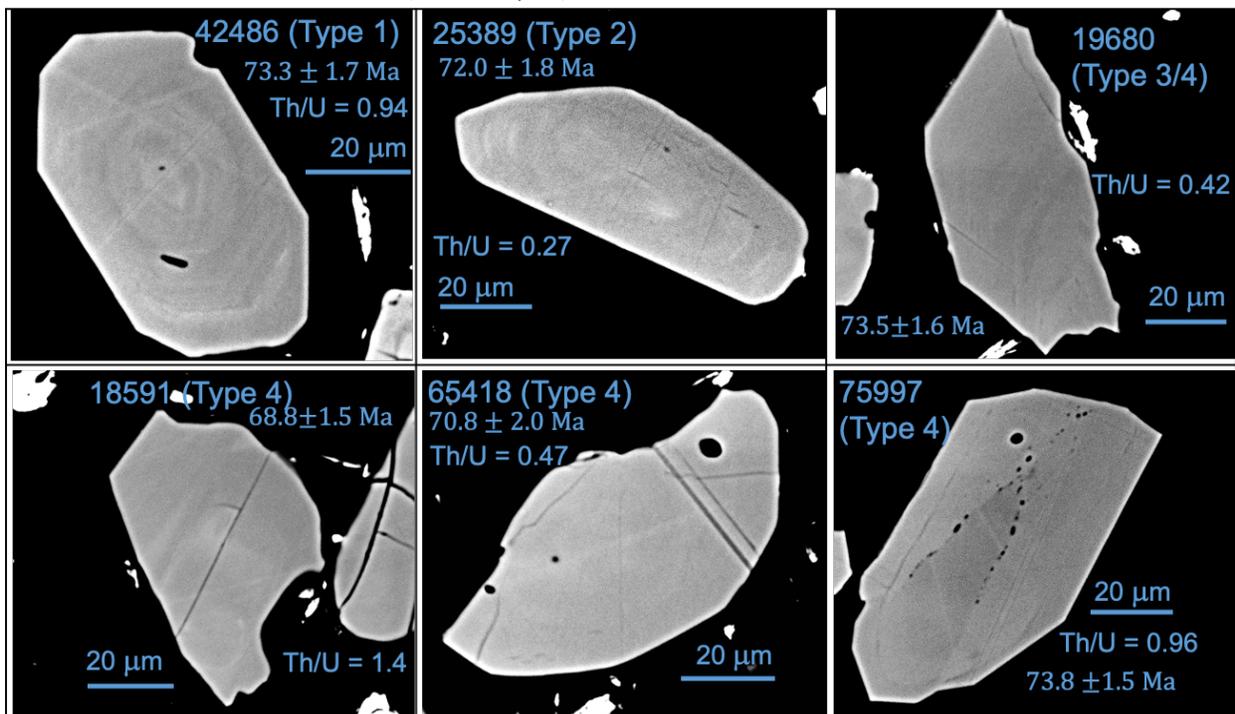

Pierre Shale Thin Sections

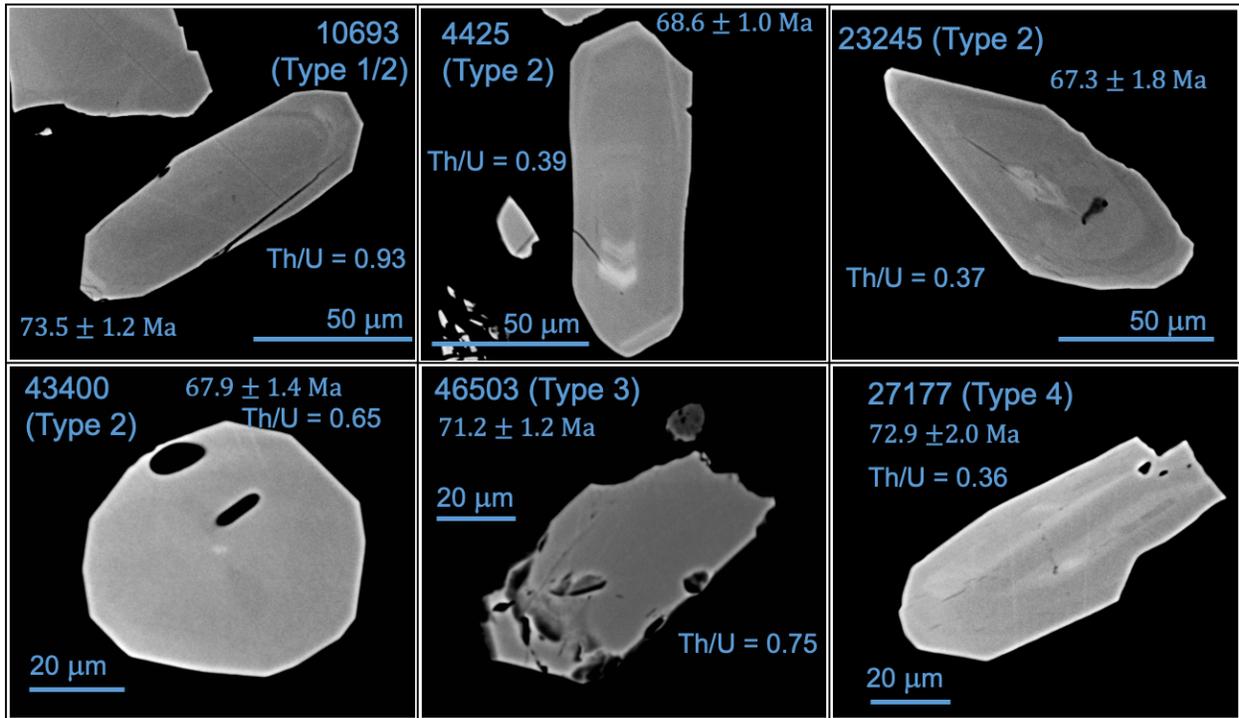

Pierre Shale Coarse Silt (20 – 63 μm) Grain Mount

Trinidad Sandstone Coarse Silt (20 – 63 μm) Grain Mount

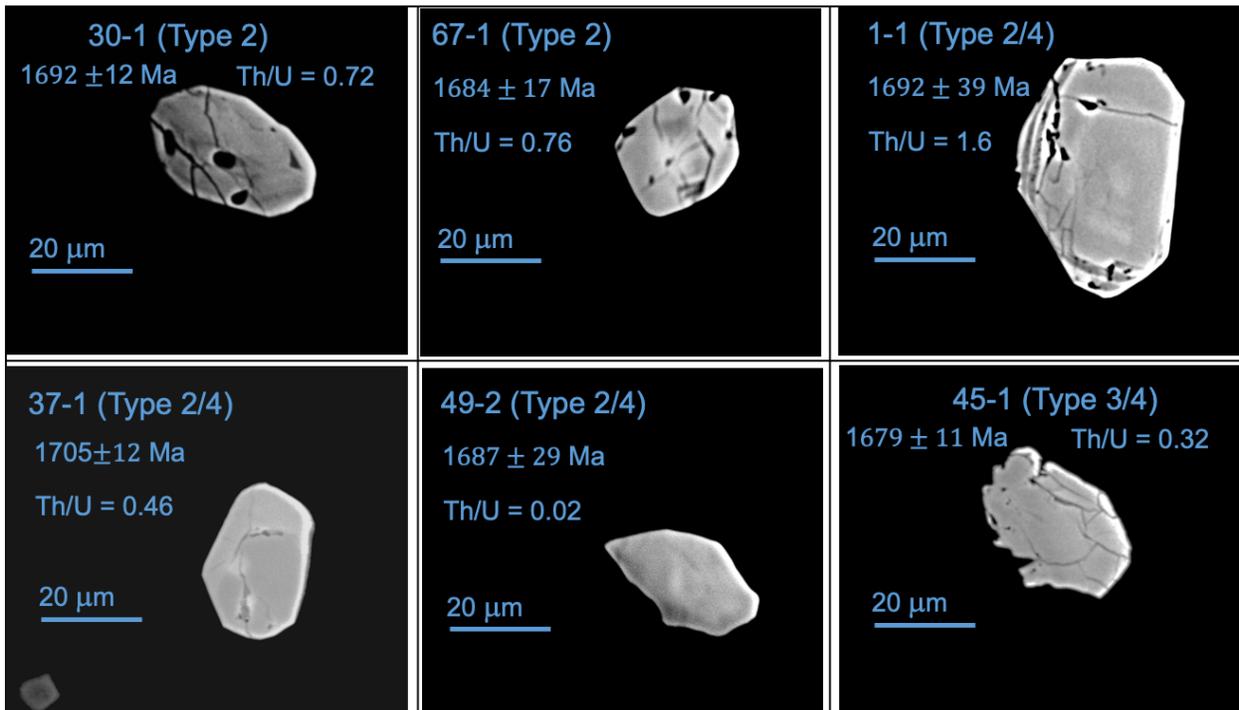

Trinidad Sandstone Very Fine Sand (63 – 125 μm) Grain Mount

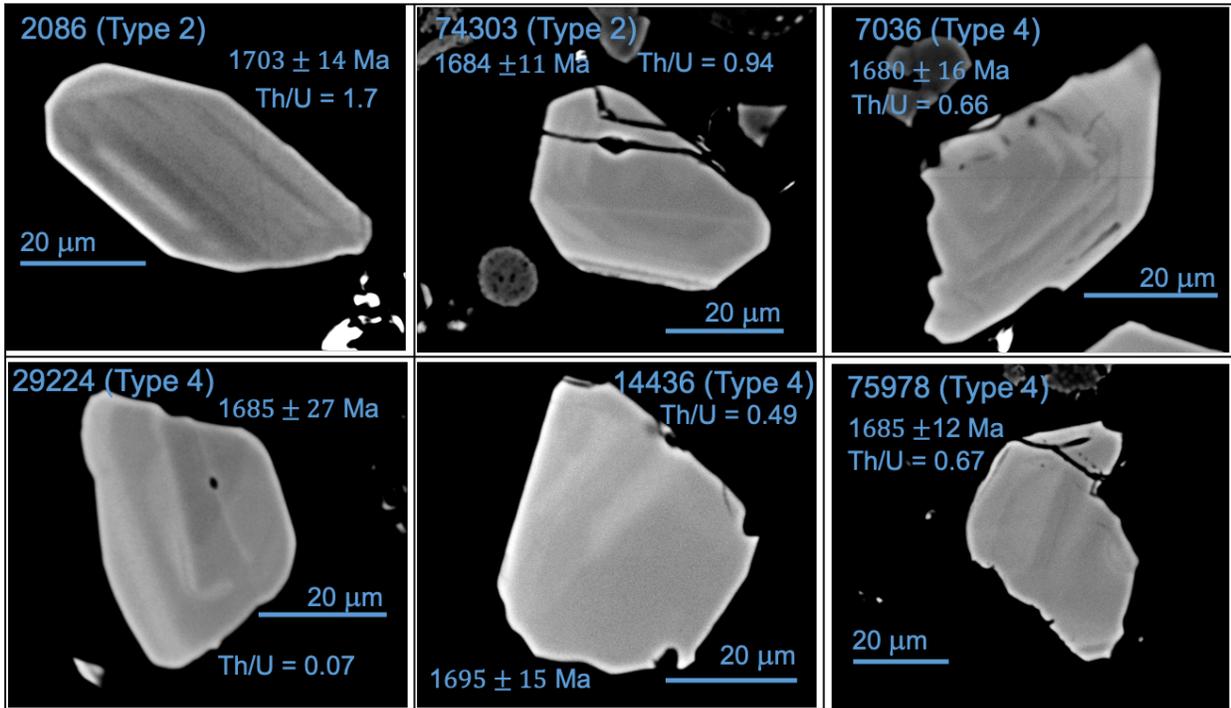

1690 ± 15 Ma Zircon Population

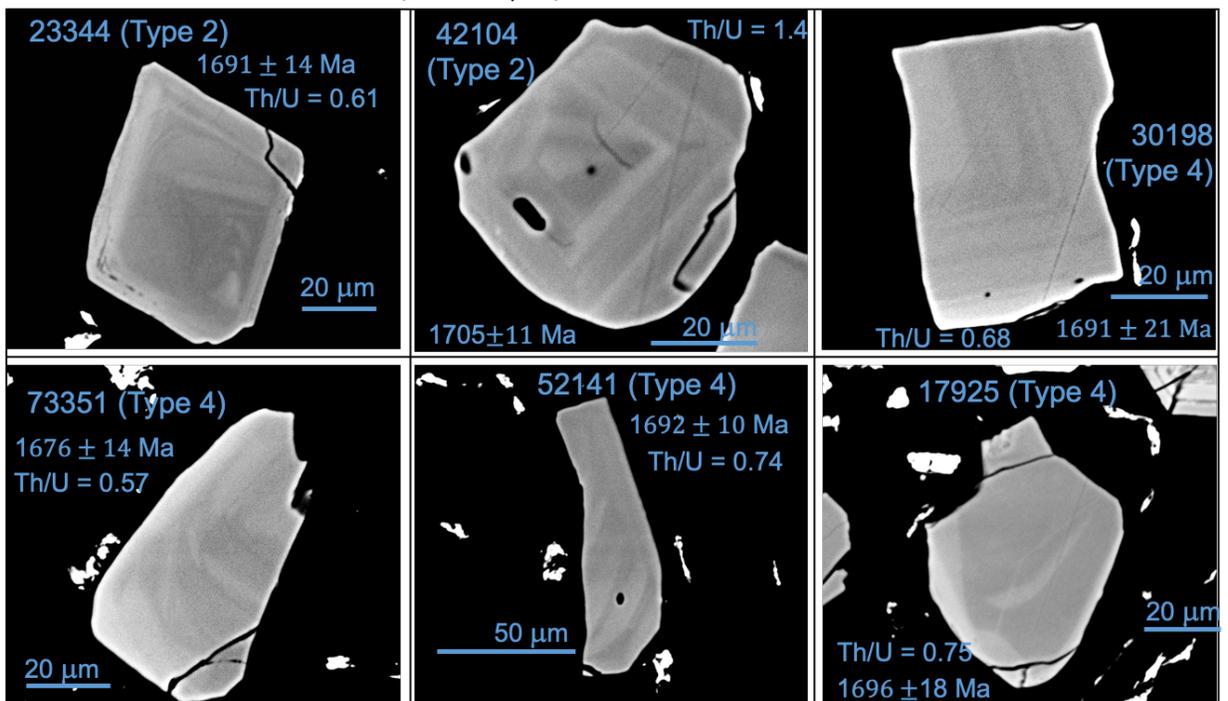

Pierre Shale Thin Sections

Pierre Shale Coarse Silt (20 – 63 μ m) Grain Mount

Trinidad Sandstone Coarse Silt (20 – 63 μ m) Grain Mount

Trinidad Sandstone Very Fine Sand (63 – 125 μm) Grain Mount

Table S1. Analytical method metadata for scanning electron microscope imaging and LA-ICP-MS U-Pb geochronology of zircon

Laboratory and Sample Preparation	
Laboratory name	Mineral Isotope Laser Laboratory (MILL), Texas Tech University
Sample type/mineral	Detrital zircons
Sample preparation	Conventional crushing and heavy liquid mineral separation, 25-mm epoxy resin mount, 1- μ m polish to finish Offcuts made into polished thin sections
Scanning Electron Microscope (SEM) Imaging	TIMA (TESCAN Integrated Mineral Analyzer): TESCAN-VEGA-3 SEM, BSE-EDX, HV: 25.0 kV, WD: 14.8 - 15.1 mm MLA (Mineral Liberation Analyzer): FEI Quanta 400 SEM, BSE-EDX, HV: 25.0 kV, WD: 11.9 – 12.3 mm
Laser ablation system	
Make, Model and type	ESI/New Wave Research, NWR193UC ArF excimer laser
Ablation cell	TwoVol2 two-volume ablation chamber
Laser wavelength (nm)	193 nm
Pulse width (ns)	5 ns
Fluence ($J\ cm^{-2}$)	2.5 $J\ cm^{-2}$ /4.25 $J\ cm^{-2}$
Repetition rate (Hz)	8 Hz
Ablation duration (s)	30 s
Spot diameter (μ m) nominal/actual	20 μ m / 12 μ m
Sampling mode / pattern	Static spot ablation
Carrier gas	100% He in the cell, Ar make-up gas combined using a Y- piece 75% along the sample transport line to the torch.
Cell carrier gas flow (He, $l\ min^{-1}$)	0.775 – 0.850 $l\ min^{-1}$
ICP-MS Instrument	
Make, Model and type	Nu Instruments, Nu AttoM ICP-MS
Sample introduction	Laser Ablation
RF power (W)	1300 W
Ar gas flows ($l\ min^{-1}$)	Cool gas (Ar) = 13.0 $l\ min^{-1}$ Aux gas (Ar) = 0.7 – 0.95 $l\ min^{-1}$ Ar make gas (Ar) = 0.65 – 0.85 $l\ min^{-1}$

Detection system	MasCom Electron Multiplier
Masses measured	202, 204, 206, 207, 208, 232, 235, 238
Integration time per peak/dwell times (ms)	200 μ s for each isotope except 400 μ s 206, 1ms 207, 2ms 235
Total integration time per output data point (s)	0.1984 s
Analysis mode/ Detection mode	Deflector jump/Pulse counting
IC Dead time (ns)	9.2 ns
Data Processing	
Calibration strategy	91500 zircon used as primary reference material, Plešovice, Temora2, Oracle, Tan Brown, OG1 and Fish Canyon Tuff zircons used as secondaries/validation
Reference material (zircon) information	91500 (Wiedenbeck et al. 1995) Plešovice (Sláma et al. 2008) Temora2 (Black et al., 2004) Oracle (Arizona LaserChron Center website, laserchron.org) Tan Brown (Bauer et al., 2020) OG1 (Stern et al., 2009) Fish Canyon Tuff (Schmitz and Bowring, 2001)
Data processing package used / Correction for LIEF	Iolite (v3.63) and VizualAge DRS (Petrus and Kamber 2012) software for data normalization, uncertainty propagation and age calculation. LIEF correction modeled using Exponential model in Iolite for 91500 zircon. Assumes reference material and samples behave identically. Ages are quoted at 2s absolute.
Common-Pb correction, composition and uncertainty	For zircons with high common Pb, ages are corrected with the Andersen (2002) method
Quality control / Validation / Concordia Ages	Plešovice (20 μ m) – 337.5 \pm 0.7 (2s, MSWD = 0.5, n = 123) Temora-2 (20 μ m) – 413.0 \pm 1.4 (2s, MSWD = 0.9, n = 83) Oracle (20 μ m) – 1437.3 \pm 7.4 (2s, MSWD = 7.4, n = 18) Tan Brown (20 μ m) – 2508.3 \pm 4.9 (2s, MSWD = 4.5, n = 41) Fish Canyon Tuff (12 μ m) – 28.74 \pm 0.49 (2s, MSWD = 0.4, n=10) Plešovice (12 μ m) – 340.7 \pm 1.7 (2s, MSWD = 0.14, n = 27) Temora-2 (12 μ m) – 423.5 \pm 3.4 (2s, MSWD = 0.4, n = 22) OG1 (12 μ m) – 3471 \pm 11 (2s, MSWD = 6.2, n=11)
