

Supplementary Information

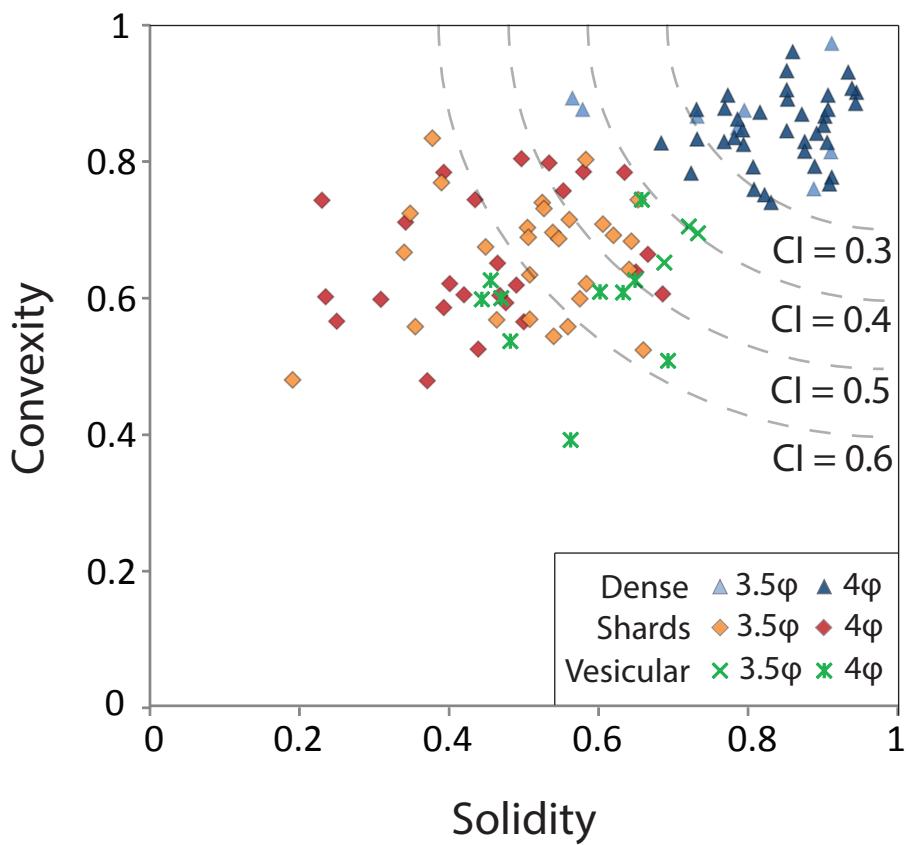

Supplementary information, Figure S1. Location map showing the 2011 vent (triangle) and sampling sites along the dispersal axis (squares). Coordinates given in Olsson et al., (2013). Samples used in this study are labelled with their distance from the vent.

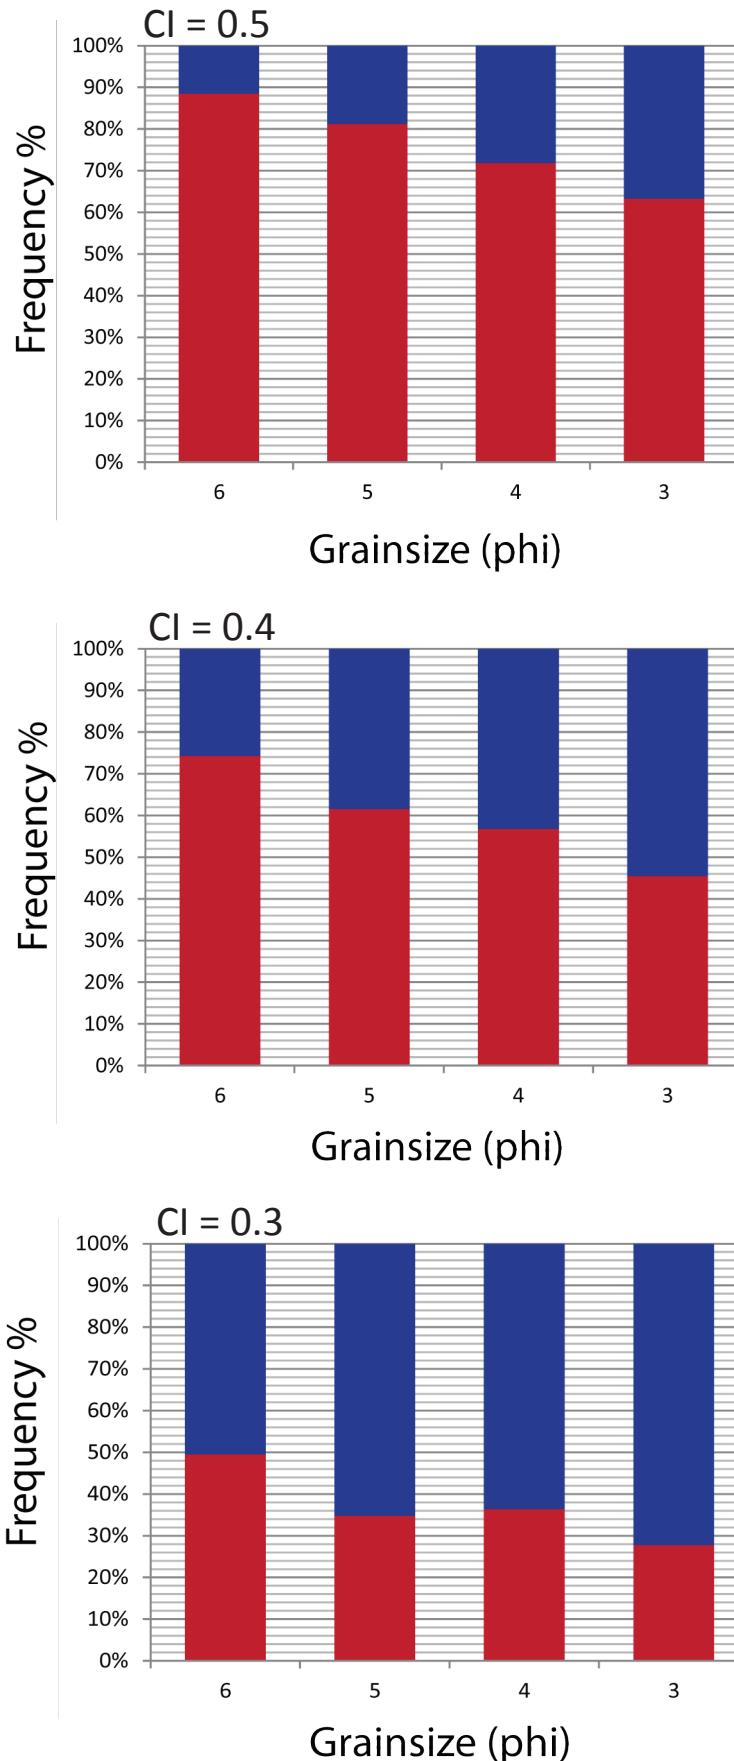

Supplementary information, Figure S2. A: measurement of vesicle diameters. We determined the maximum dimension (red lines) of 250 bubbles per size fraction from BSE grid images, including all vesicles $>2\text{ }\mu\text{m}$ that preserved at least 50% of the bubble wall. B: The smooth concave curvature on even the largest shards provides evidence of some larger vesicles that are not captured by our measured VSD. The dashed orange lines illustrate the convex hull for the two particles shown in A and B. The convex hull perimeter is like stretching an elastic band around a particle, and is equivalent to the particle outline for a fully convex shape.

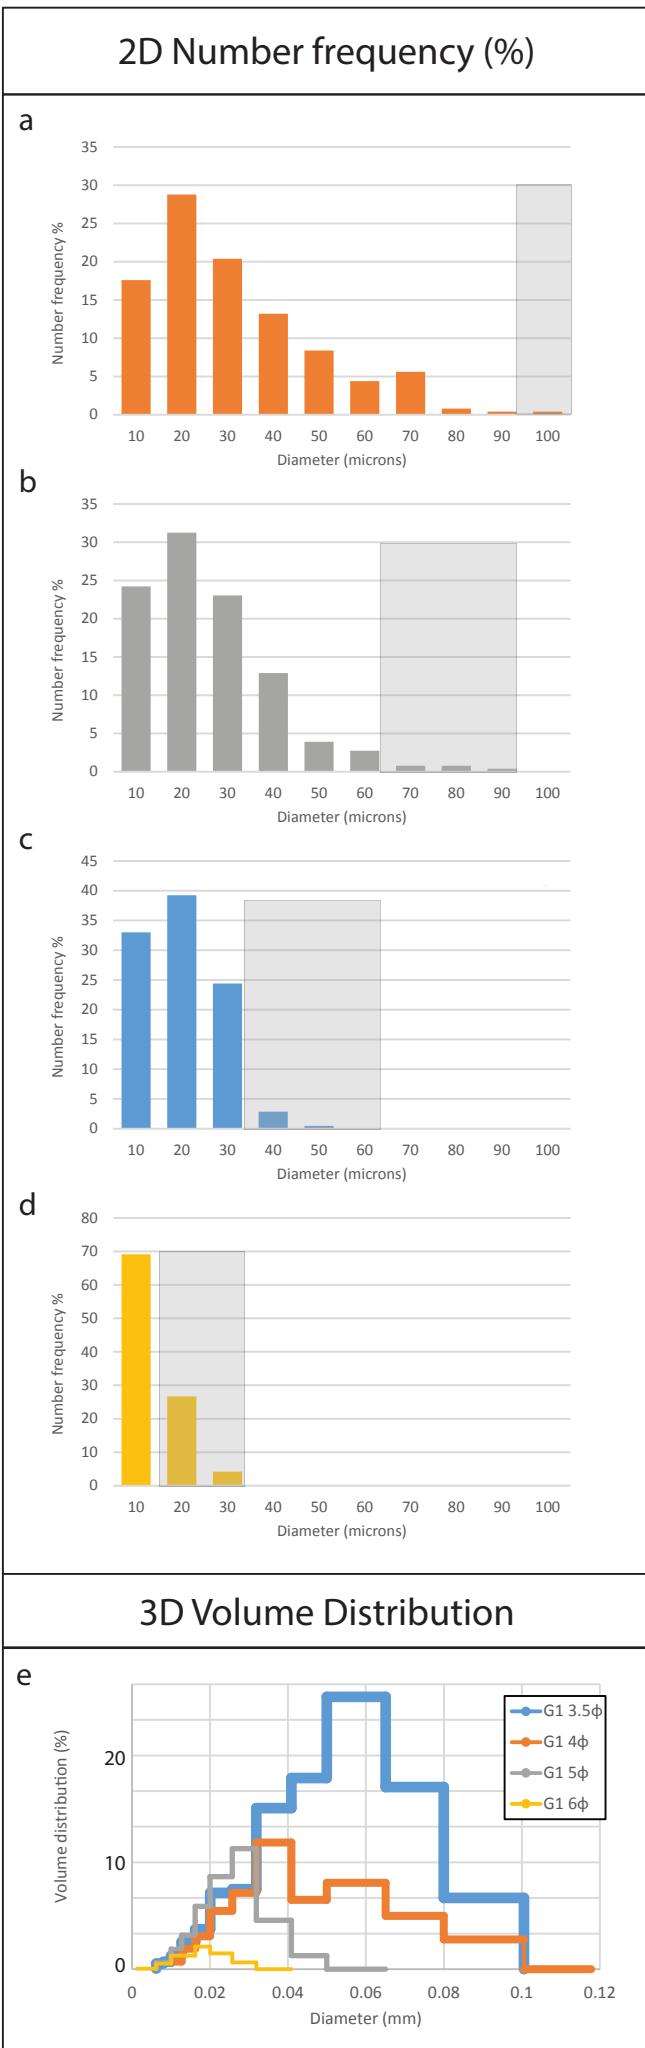

Supplementary Figure S3. Surface fracture patterns (river-lines), resulting from brittle fragmentation under mixed-mode stresses (Hull, 1999).

Supplementary information, Figure S4. Origin of the *concavity index*, (CI ; Eq. 1). Solidity (S) and convexity (C) values are shown for a subsample of ash particles from G6 and G1 ($<3.5\phi$ and 4ϕ). CI is the magnitude of the vector from a perfect circle ($S=C=1$). The dashed lines show CI contours.

Supplementary information, Figure S5. Sensitivity of automated componentry to C_l threshold. Manual componentry shown in Figure 3 for comparison. Red and blue bars correspond to dense fragments and bubbly grains (vesicular particles and shards), respectively.

Supplementary information, Figure S6.

A-D: Comparison of 2D number frequency of bubble diameters recorded by each ash size fraction (shaded regions indicate size range of particles). The distribution preserved in the coarsest ash fraction does not appear to be truncated, and therefore provides a representative measure of the lower end of the bubble size distribution. E: 3D bubble volume distributions recorded by each ash size class. Distributions are shown as percentages of the total bubble volume. For smaller size classes (4, 5 and 6 phi), distributions are shown as percentages of the total volume of bubbles smaller than the maximum grain size in each size class. Line colours refer to the same particle size classes as shown in A-D.

Supplementary Information

Table S1: Table S1: EPMA glass analyses of ash grains (1 analysis per particle) from the 3φ size fraction of G1 (analyses 1–15) and G6 (analyses 16–28) Grimsvötn samples (22 May 2011).

Table S2: Number of particles analysed per size fraction for automated componentry.

Automated BSE grid images, each containing 1159–3769 particles in 20–40 images, were acquired for each sample size fraction, with the acquisition magnification set for a minimum resolution of 500 pixels/particle; the average resolution for all size fractions is 2211 pixels/particle. High resolution (average ~20,000 pixels/particle; ≤ 81 images) grids of samples G6 (3.5φ and 4φ) and G1 (4φ) allowed us to test the sensitivity of the shape parameters to image resolution. All images were obtained using a Hitachi S-3500N SEM at the University of Bristol, UK.

| Sample | 3.5φ | 4φ | 5φ | 6φ |
|--------|------|------|------|------|
| G1 | 1157 | 2674 | 2687 | 2423 |
| G3 | 2439 | 1489 | 1578 | 1489 |
| G4 | 1828 | 1398 | 1086 | 1220 |
| G6 | 1159 | 1267 | 2570 | 2873 |
| G7 | 2628 | 1219 | 1902 | 2249 |
| G8 | 2691 | 1424 | 1425 | 1625 |

Table S3: Grain size distribution data tables. This file contains the raw data and corresponding references for the grain size distributions shown in Figure 1.
