Jian-Kang Yi, Di-Cheng Zhu*, Roberto F. Weinberg, Qing Wang, Jin-Cheng Xie, Liang-Liang Zhang, Zhi-Dan Zhao. Origin of Tibetan post-collisional high-K adakitic granites: anatexis of intermediate to felsic arc rocks

1. Supplemental Figures

Figure S1

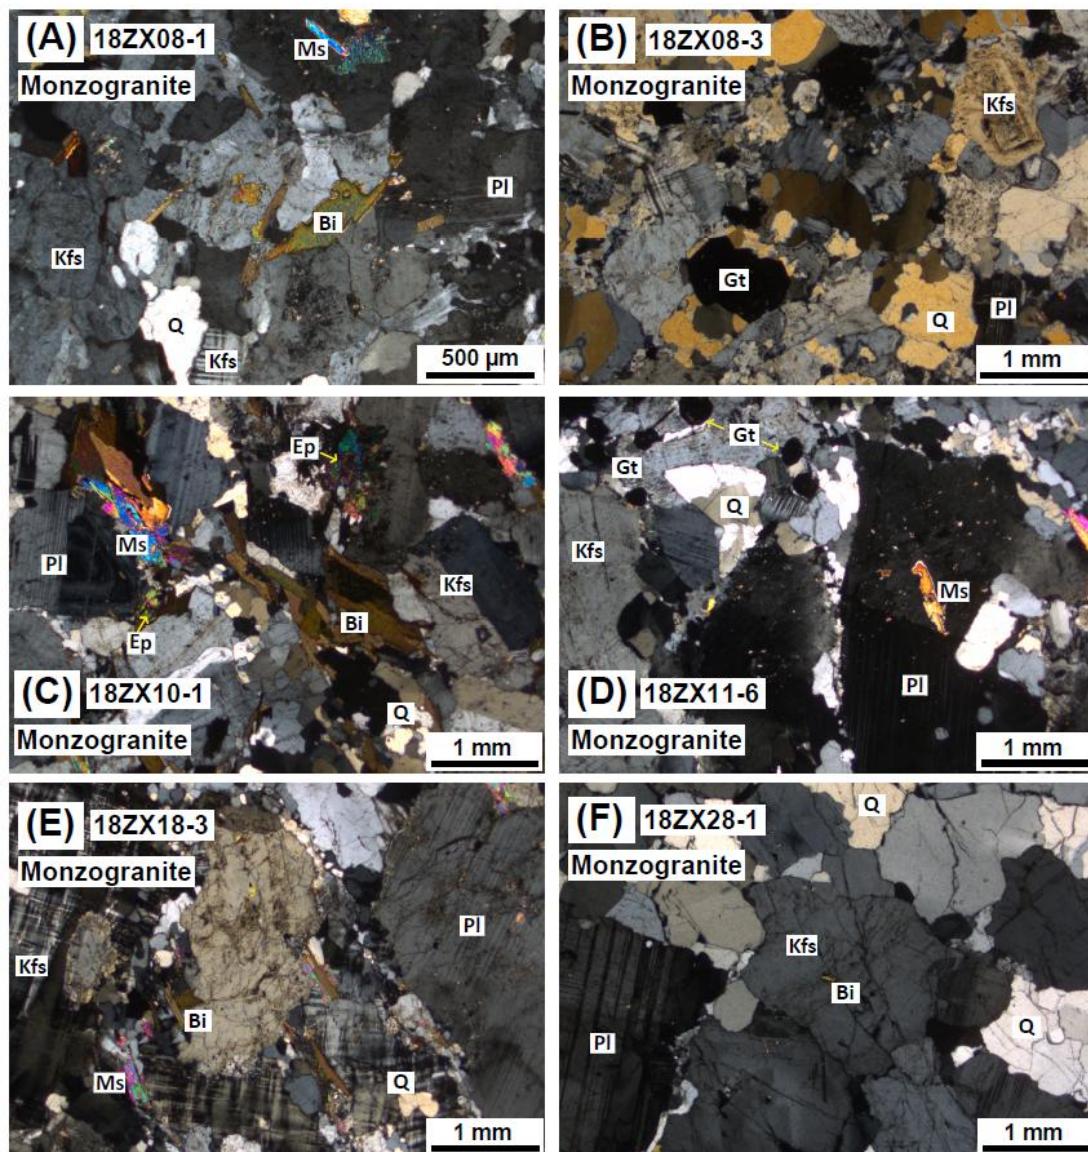

Figure DR1. Photomicrographs of post-collisional high-K adakitic granites from the

Zharao Pluton in eastern Gangdese belt. Abbreviations: Bi = biotite, Gt = garnet, Ms= muscovite, Ep = epidote, Kfs = K-feldspar, Pl = plagioclase, Q = quartz. High-K adakitic granites are mainly monzogranites with minor biotite ± muscovite ± garnet ± epidote. The mafic mineral abundance in these rocks is low, generally less than 5%. No amphibole was found in any granite sample.

Figure S2

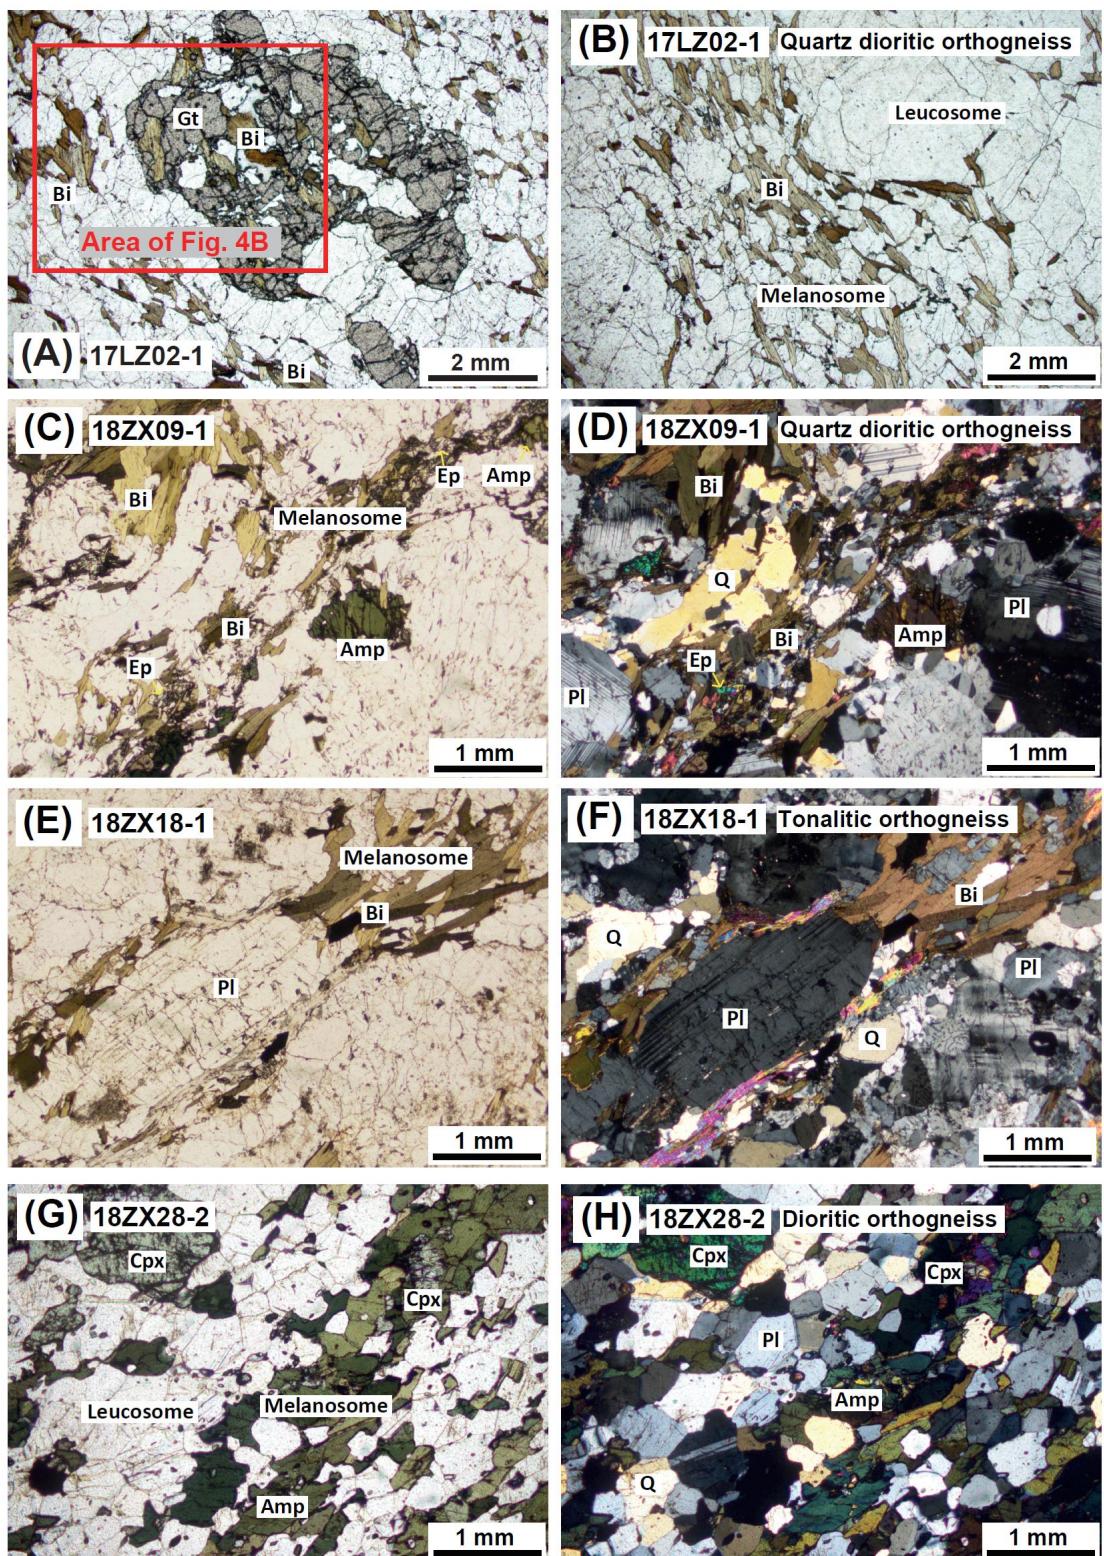

Fig. DR2 Photomicrographs of syn-collisional migmatitic intermediate-felsic orthogneiss samples, showing (a) foliation and gneissic structure of the dioritic, quartz dioritic and tonalitic orthogneisses, comprising melanosome and leucosome, (b)

biotite as the dominant mafic mineral in the melanosome, (c) general mineral assemblage of the orthogneisses consisting of biotite, garnet, amphibole, plagioclase, quartz and minor epidote and clinopyroxene. Abbreviations: Bi = biotite, Gt = garnet, Amp = amphibole, Pl = plagioclase, Q = quartz, Ep = epidote, Cpx = clinopyroxene.

Figure S3

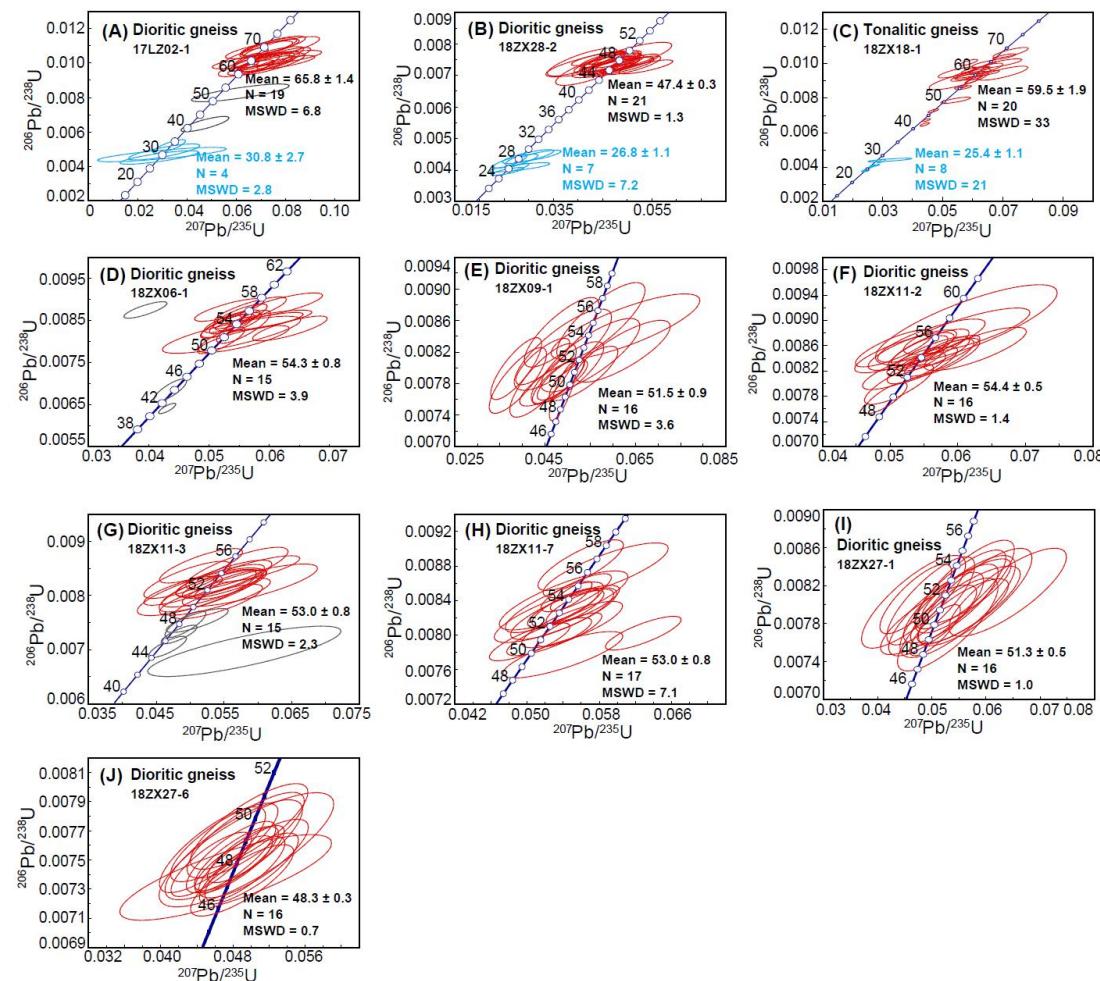

Fig. DR3 Laser ablation-inductively coupled plasma-mass spectrometry (LA-ICP-MS) U-Pb zircon ages of migmatitic orthogneisses. The samples have syn-collisional magmatic protolith ages of 66–48 Ma, and samples in F and I also yield younger Oligocene zircon rims indicating the time of anatexis.

Figure S4 (part 1)

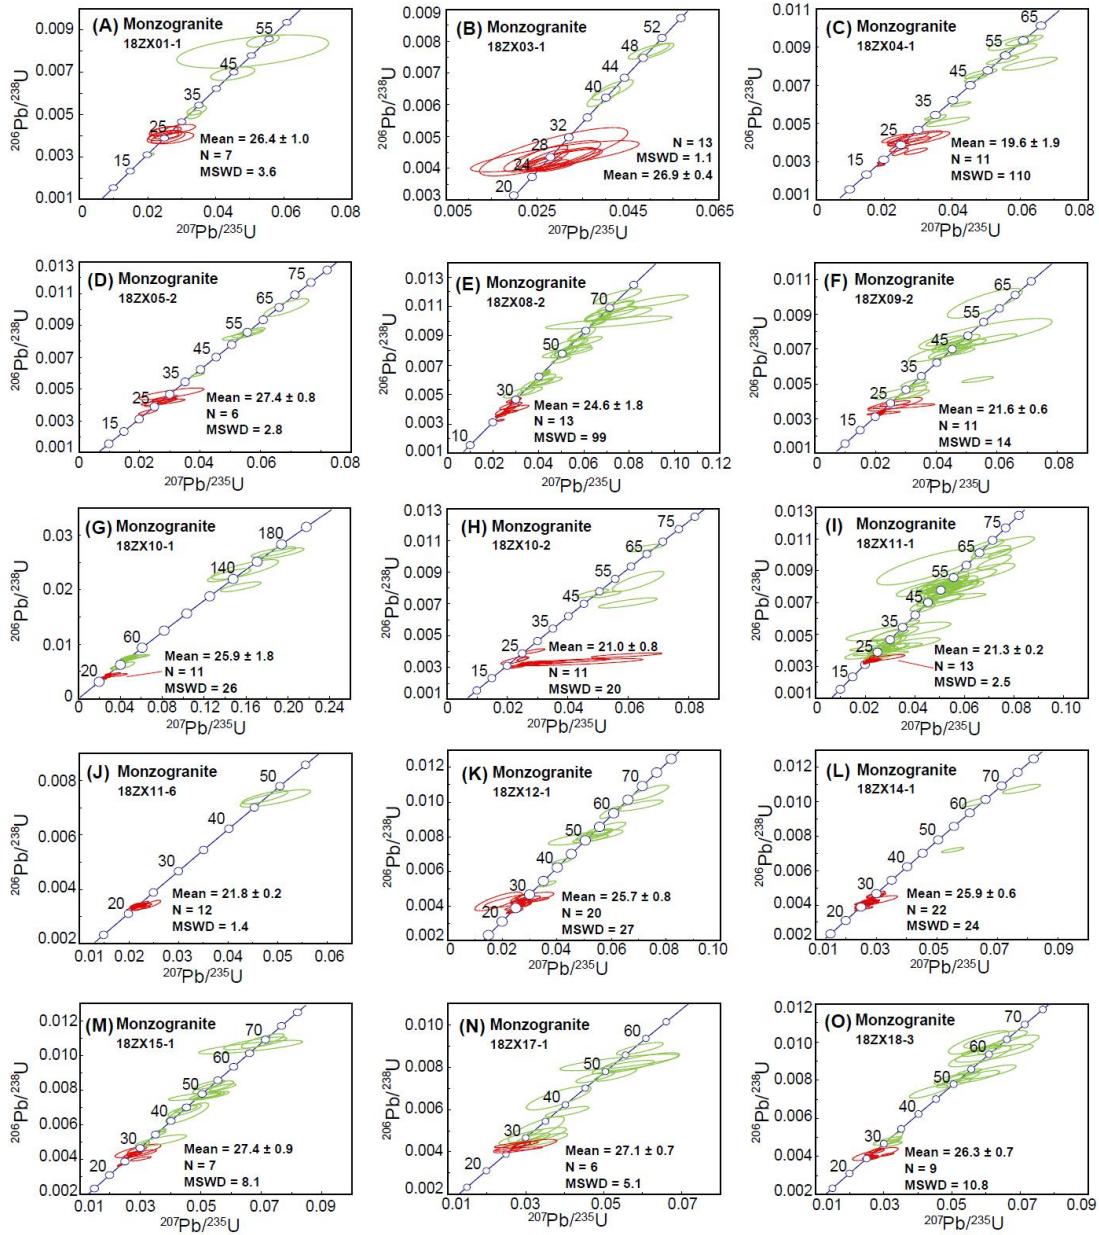

Figure DR4. Laser ablation-inductively coupled plasma-mass spectrometry (LA-ICP-MS) U-Pb zircon ages of Oligocene granites. Two age groups of 66–48 Ma and 30–22 Ma have been identified.

Figure S4 (part 2)

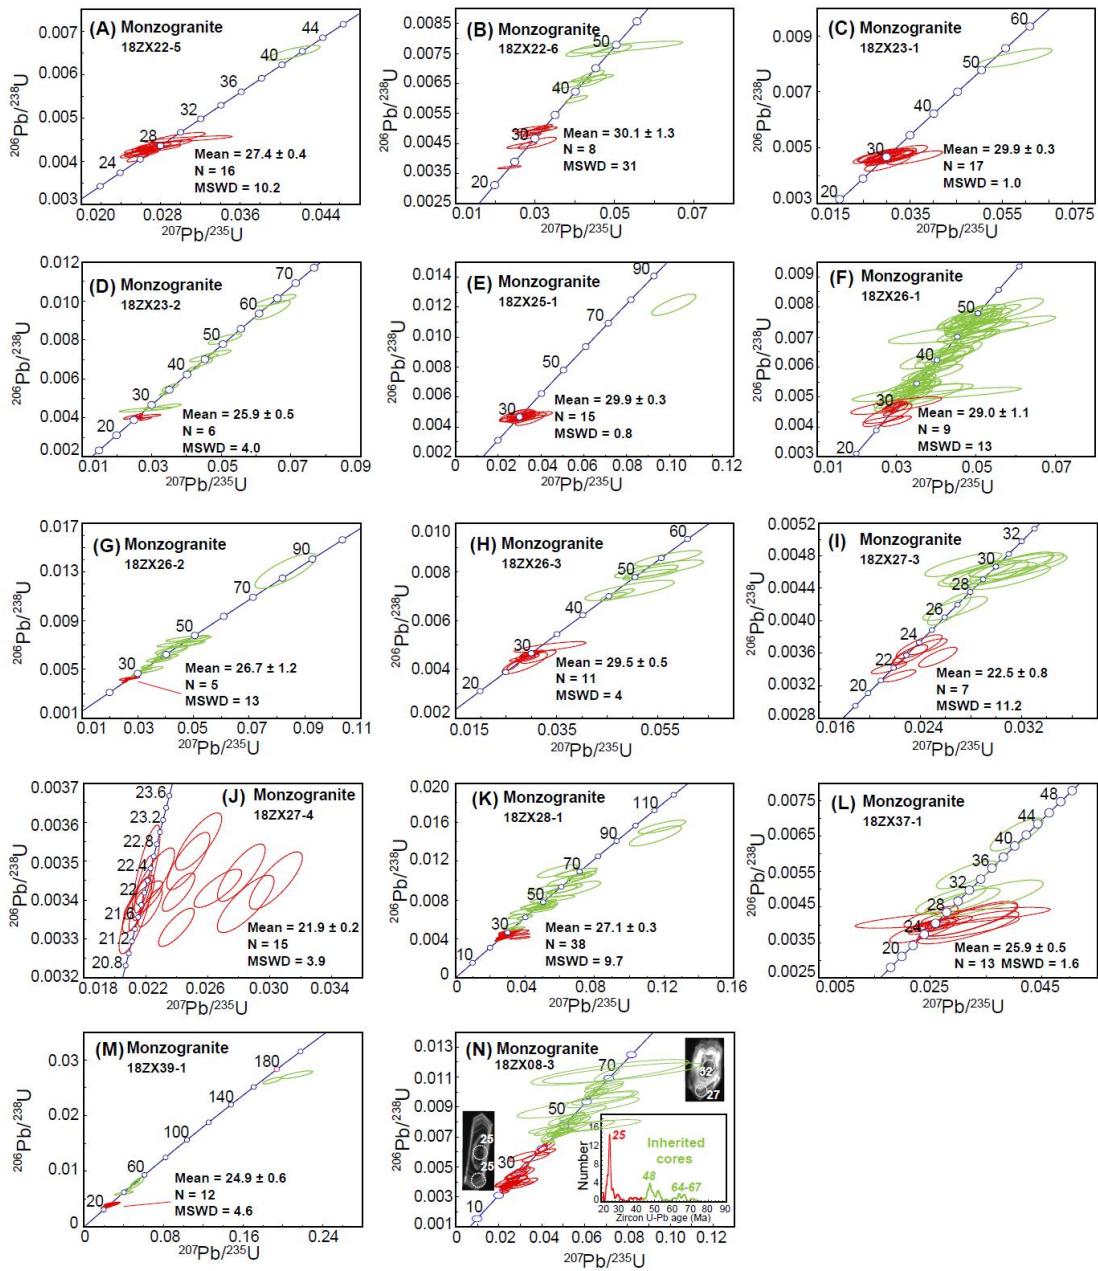

Figure DR4. Laser ablation-inductively coupled plasma-mass spectrometry (LA-ICP-MS) U-Pb ages of Oligocene granites. Two age groups of 66–48 Ma and 30–22 Ma have been identified.

Figure S5

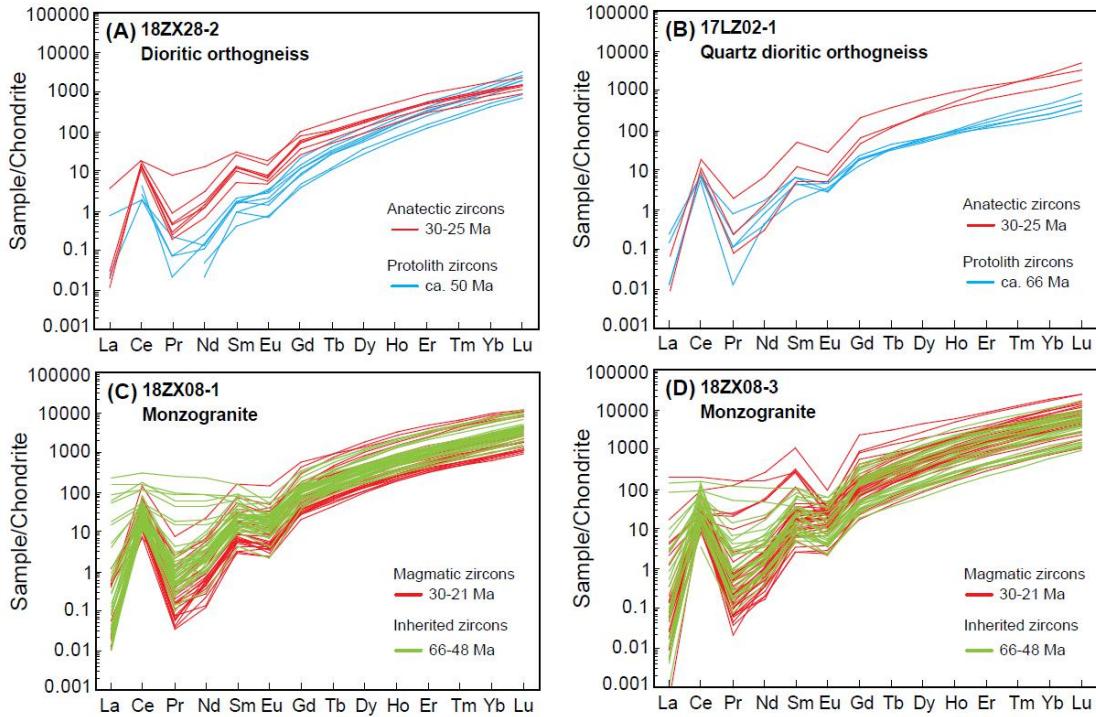

Figure DR5. REE patterns of zircons from post-collisional monzogranites and syn-collisional orthogneisses. Chondrite normalizing values were taken from [Sun and McDonough \(1989\)](#).

2. Methods

3.1. LA-ICP-MS zircon U-Pb dating

Zircons were separated from the crushed samples using standard density and magnetic separation techniques in the Laboratory of the Geological Team of Hebei Province, China. The separated zircons were handpicked under a binocular microscope and mounted in epoxy resin, which was then polished until the grain

centers were exposed. Cathodoluminescence (CL) images were obtained using an electron microprobe at the Institute of Geology and Geophysics, China Academy of Sciences (IGGCAS) in Beijing, China, to identify the internal zoning and textures of the zircons.

Zircon LA–ICP–MS U–Pb dating and trace element analyses were conducted synchronously at the Mineral Laser Microprobe Analysis Laboratory (Milma Lab), China University of Geosciences, Beijing (CUGB), China. Laser sampling was performed using a NewWave 193UC excimer laser ablation system. The ablated material was transported by carrier gas into the plasma source of an Agilent 7900 ICP–MS. Detailed setting parameters for the laser ablation system and the ICP–MS instrument are listed in the table below.

Nitrogen was used as a protective gas to prevent energy loss during beam transmission. The laser has a TwoVolume 2 sample cell that is 10 cm × 10 cm × 3 cm in volume. Helium was used as the carrier gas and argon was used as the make-up gas, and they were mixed together by a tubular smoother before entering the ICP. The carrier and make-up gas flows were optimized by a line scan (speed: 5 μm/s; spot size: 25 μm) ablating NIST SRM 610 to obtain maximum signal intensity for ^{238}U (generally >106 counts per second), while minimizing ThO/Th (<0.2) and Ca²⁺/Ca⁺ (<0.7) to reduce matrix-induced interference. To ensure complete atomization and ionization, the ion-signal intensity ratio of ^{238}U and ^{232}Th was measured to approximate 1 for NIST SRM 610. The ^{204}Hg gas background needed to be lower than 400 counts per second for the high-purity argon and helium. ^{204}Pb was unaffected by the presence of ^{204}Hg on account of the background being measured on peaks.

Each analysis consisted of one 18 s integration on peaks with laser warm-up (for background), 50 s integration with the laser firing, and 10 s washout to purge the previous sample and prepare for the next analysis. Agilent MassHunter software was utilized for the acquisition of each analysis. Off-line selection and integration of background and analyte signals, and time-drift correction and quantitative calibration for trace element analyses and U–Pb dating were performed using ICPMSDataCal software ([Liu et al., 2008](#)). NIST SRM 610 and ^{91}Zr were used as external reference

material and internal standard, respectively, for calibrating the trace element concentrations. Common Pb corrections were calculated using ComPbCorr#3.17. Concordia diagrams and $^{206}\text{Pb}/^{238}\text{U}$ weighted mean plots were made using Isoplot. Spot size of 25 μm was used for the U-Pb dating.

Zircon 91,500 was used as an external standard for correcting mass discrimination and elemental fractionation for U-Pb dating. The external standard was analyzed twice every 6–8 analyses of zircon samples. Zircon standards GJ-1 and Plesovice were analyzed as unknown samples that were inserted between 91,500 and the samples (e.g., 2 zircon 91,500 + 1 zircon GJ-1 + 1 zircon Plesovice +6–8 samples +2 zircon 91,500). We obtained weighted mean $^{206}\text{Pb}/^{238}\text{U}$ ages of 599.2 ± 4.6 Ma (2SD, n = 4) for GJ-1 and 336.8 ± 2.9 Ma (2SD, n = 4) for Plesovice, which are within error of recommended values ([Jackson et al., 2004](#); [Slama et al., 2008](#)).

Typical operation conditions for LA-ICP-MS analysis in Milma Lab:

ICP-MS conditions	
RF power	1350 W
Sampling depth	7.0 mm
Plasam gas	15 L/min
Auxiliary gas	1 L/min
Make-up gas	0.8 L/min
Dwell time	
^{204}Pb	20 ms
^{206}Pb	20 ms
^{207}Pb	30 ms
^{208}Pb	15 ms
^{232}Th	10 ms
^{238}U	15 ms
Other element	6 ms
Laser parameters	
Wavelength	193 nm
Pulse duration	5 ns
Ablation style	Single spot
Energy density	2-4 J/cm ²
Carrier gas (He)	800-900 ml/min
Ablation spot size	35 μm
Repetition rate	6 Hz

3.2. Zircon Hf isotopic analysis

In-situ zircon Hf isotopic analyses were conducted using a Neptune Plus MC-ICP-MS (Thermal Fisher Scientific, Germany), coupled to a New Wave 193 excimer ArF laser-ablation system at the Milma Lab, China University of Geosciences (Beijing) with a beam size of 35 µm, laser pulse frequency of 8 Hz and energy density of 3.7 J/cm². Makeup gas of argon and carrier gas of helium with the addition of nitrogen mixed in a T-branch pipe prior to introduction into the MC-ICP-MS. In the experiment, L4 to H3 Faraday cups were used to collect ¹⁷¹Yb, ¹⁷³Yb, ¹⁷⁵Lu, ¹⁷⁶Hf, ¹⁷⁷Hf, ¹⁷⁸Hf, ¹⁷⁹Hf, and ¹⁸⁰Hf, respectively with the integration time of 0.131 s. The carrier and makeup gas flows were optimized by a line scan (spot size of 35 µm and scan speed of 5 µm/s) ablating NIST SRM 610 to obtain maximum signal intensity for ²³²Th, while minimizing ²³²Th/¹⁶O/²³²Th ratio. For each analysis, 50 s integration for gas blank and 50 s integration for signal collection were set up with a total of 800 cycles of raw data. Zircon 91500 (Blichert-Toft, 2008) was used as an external standard for correcting mass discrimination. Zircon standard Plešovice (Sláma et al., 2008) and GJ-1 (Morel et al., 2008) were analyzed as unknown sample that were inserted between zircon 91500 and the samples. Raw data was converted by Neptune Plus software and the then performed using Iolite software (Paton et al., 2011).

The initial ¹⁷⁶Hf/¹⁷⁷Hf ratios and $\epsilon_{\text{Hf}}(t)$ values were calculated with the reference to the chondritic reservoir (CHUR) at the time of zircon growth from the magmas. The decay constant for ¹⁷⁶Lu of 1.867×10^{-11} year⁻¹ (Söderlund et al., 2004), the chondritic ¹⁷⁶Hf/¹⁷⁷Hf ratio of 0.282785 and ¹⁷⁶Lu/¹⁷⁷Hf ratio of 0.0336 (Bouvier et al., 2008) were adopted. Depleted mantle model ages (T_{DM}) were calculated with reference to the depleted mantle at a present-day ¹⁷⁶Hf/¹⁷⁷Hf ratio of 0.28325, and ¹⁷⁶Lu/¹⁷⁷Hf = 0.0384 (Griffin et al., 2000). The Hf isotope crustal model age (T_{DM}^{C}) was calculated by assuming that its parental magma was derived from an average

continental crust, with $^{176}\text{Lu}/^{177}\text{Hf} = 0.015$, that originated from the depleted mantle source ([Griffin et al., 2002](#)).

3.3. Whole-rock geochemical analysis

Fresh rocks samples were crushed, hand-picked, and then powdered using an agate mill to a grain size < 200 mesh at the Yuneng Mineral Separation Service Company at Langfang, Hebei Province, China.

Major element analyses of whole rock were conducted on Agilent 7700e ICP-MS at the Wuhan SampleSolution Analytical Technology Co., Ltd., Wuhan, China. The sample pretreatment of whole rock major element analysis was made by melting method. The flux is a mixture of lithium tetraborate, lithium metaborate and lithium fluoride (45:10:5), Ammonium nitrate and lithium bromide were used as oxidant and release agent respectively. The melting temperature was 1050 °C and the melting time was 15minutes.

Weighing reagents	Weighing weight
45Li ₂ B ₄ O ₇ :10LiBO ₂ :5LiF	6.0000±0.0002 g
NH ₄ NO ₃	0.30±0.001
sample	0.6000±0.0001 g

Zsx Primus II wavelength dispersive X-ray fluorescence spectrometer (XRF) produced by RIGAKU, Japan was used for the analysis of major elements in the whole rock, The X-ray tube is a 4.0Kw end window Rh target, The test conditions are voltage: 50kV, current: 60mA. All major element analysis lines are ka . The standard curve uses the national standard material of China, rock standard sample: GBW07101-14, soil standard sample: GBW07401-08, stream sediment standard sample: GBW07302-12. The data were corrected by theoretical α coefficient method. The relative standard deviation (RSD) is less than 2%.

Trace element analyses of whole rock were conducted on Agilent 7700e ICP-MS at the Wuhan SampleSolution Analytical Technology Co., Ltd., Wuhan, China. The detailed sample-digesting procedure was as follows: (1) Sample powder (200 mesh)

was placed in an oven at 105 °C for drying of 12 hours; (2) 50 mg sample powder was accurately weighed and placed in a Teflon bomb; (3) 1 ml HNO₃ and 1 ml HF were slowly added into the Teflon bomb; (4) Teflon bomb was putted in a stainless steel pressure jacket and heated to 190 °C in an oven for >24 hours; (5) After cooling, the Teflon bomb was opened and placed on a hotplate at 140 °C and evaporated to incipient dryness, and then 1 ml HNO₃ was added and evaporated to dryness again; (6) 1 ml of HNO₃, 1 ml of MQ water and 1 ml internal standard solution of 1 ppm In were added, and the Teflon bomb was resealed and placed in the oven at 190 °C for >12 hours; (7) The final solution was transferred to a polyethylene bottle and diluted to 100 g by the addition of 2% HNO₃.

3.4. Mineral geochemistry

Major element analyses of silicate minerals were carried out using JEOL JXA-8100 (a beam current of 20 nA at 15 kV) and EPMA-1720 (a beam current of 10 nA at 15 kV) electron microprobes at the EMPA Laboratory of China University of Geosciences (Beijing). The resolution of electron beams is 1-2 µm for both. Natural minerals and synthetic pure oxides, which were provided by SPI Company USA, were used as standards. The analytical errors are generally less than 2%.

3.5. Phase equilibrium modeling

All equilibria used Perple_X ([Connolly, 2005](#); version 6.7.4) and an internally consistent thermodynamic dataset of [Holland and Powell \(1998\)](#) in the system MnO–Na₂O–CaO–K₂O–FeO–MgO–Al₂O₃–SiO₂–H₂O–TiO₂ (MnNCKFMASHT). Ferric iron was omitted from the model system and the fluid was considered as pure H₂O. The following activity-composition relations were used for modeling: biotite ([Tajčmanová et al., 2009](#)), garnet ([White et al., 2007](#)), amphibole ([Diener et al., 2007](#)), feldspar ([Fuhrman and Lindsley, 1988](#)), white mica ([Coggon and Holland, 2002](#)), cordierite and staurolite ([Holland and Powell, 1998](#)), ilmenite ([White et al., 2007](#)),

chlorite and chloritoid (White et al., 2014), and silicate melt (White et al., 2001). When modeling peritectic garnet compositional isopleths, $X_{\text{Mg}} = \text{Mg}/(\text{Mg} + \text{Fe}^{2+} + \text{Ca} + \text{Mn})$, $X_{\text{Fe}} = \text{Fe}/(\text{Mg} + \text{Fe}^{2+} + \text{Ca} + \text{Mn})$ were used.

3. Analytical Data

All 41 samples were analyzed for whole-rock chemistry. Whole-rock Sr and Nd isotopes were determined for 7 granitic and 5 migmatitic orthogneiss samples (Table S1). LA-ICP-MS zircon U-Pb dating has been performed on 40 of the 41 samples, with 979 dating spots for 30 granites and 241 spots for 10 migmatitic orthogneisses (Table S2). A total of 205 dated zircon domains from 3 granitic and 4 migmatitic orthogneiss samples were selected for LA-MC-ICP-MS Lu-Hf isotopic analysis (Table S3). Major element analyses of peritectic garnets of one migmatitic orthogneiss sample were carried out using electron microprobe (Table S4).

Table S1. Whole-rock major and trace element data and Sr-Nd isotopic data for Zharaо monzogranites and migmatitic orthogneisses
