## Supplemental Material

**Text.** Analytical Methods. Regional geological summary. Zircon age compilation. Statistical testing of zircon U-Pb spectra.

**Figure S1.** Grain size spectra for the sample as considered within the study showing the variability between A) the modern river and B) Holocene-historical samples. All samples are classified as dominantly silt to fine sand.

**Figure S2.** (A) Geochemical classification of sediments from this study following the scheme of Herron (1988). (B) Plot of  $\text{Al}_2\text{O}_3/\text{SiO}_2$  versus  $\text{Fe}_2\text{O}_3/\text{SiO}_2$  for sediments from the Mississippi River after Singh et al. (2005). Lower ratios indicate an increase of the quartz proportion and a depletion of phyllosilicates. The linear trend corresponds to mineralogical sorting of these sediments during fluvial transport. The star corresponds to average Upper Continental Crust (UCC)(Taylor and McLennan, 1995). Modern tributary data from Gregory et al. (2022).

**Figure S3.** Kernel density estimate (KDE) diagrams showing the age distribution of the major basement tectonic blocks of North America that may be supplying sediment to the Mississippi River. Band width 15 m.y. Data are compiled from the literature and summarized in the online data supplement.

**Figure S4.** (A) KDE plots comparing three samples that were analyzed first with a moderate number of grains and them with an expanded number in order to understand the impact of large sample size on the result. (B) Multidimensional Scalar Diagram (MDS) comparing the small and large sediment samples with potential source regions. The analysis demonstrates that increasing the sample size has only a moderate impact on the final result.

**Figure S5.** Figures showing cumulative frequency diagrams for each of the sediment samples considered here with the black line showing the observed spectrum and the colored lines showing the top 1% of models for each sample based on the stated statistical method employed. When the models largely overlap with the observed spectrum the preferred model can be considered statistically robust.

**Figure S6.** Estimated contributions from the major continental source terrains for each sample as calculated from the DZMix software of Sundell and Saylor (2017) using the Kuiper statistical test to estimate the contributions.

**Figure S7.** (A) A dissimilarity matrix comparison of the zircon age spectra for the different detrital sediment samples compared with LGM sediments from the Gulf of Mexico (Fildani et al., 2016), modern major tributaries from Gregory et al. (2022) and basement sources compiled from the various terrains for the source regions to the Mississippi River. Note the dissimilarity of most of the sediments with the Appalachian, Trans-Hudson and Superior provinces, but the strong similarity of many samples with the Rocky Mountain foreland. (B) A dissimilarity matrix of only the LGM and younger sediments emphasizing differences between the lower river in recent geological time.

**Figure S8.** Radial plots of equivalent dose (DE) distributions.

**Table S1.** Raw data output from laser particle size analyzer for the sediments considered in this study.

**Table S2.** Isotope data taken from the analyses of single zircon grains within the various samples considered in the study.

**Table S3.** Results of Monte Carlo mixing simulations for zircon age spectrum for the samples considered in the study as analyzed using DZMix software of Sundell and Saylor (2017).

**Table S4.** Dose rate information for the OSL samples. 1 Assumed 20 } 6% as moisture content over burial history. 2 Radio-elemental concentrations determined using ICP-MS and ICP-AES techniques; dose rate is derived from average of concentrations by conversion factors from Guerin et al. (2011).

**Table S5.** Geochemical analyses of the OSL samples. Trace element concentrations are in ppm, major elements in weight %.

Climate and Anthropogenic Impacts on North American Erosion and Sediment Transport since the Last Glacial Maximum: Evidence from the Zircon Detrital Record of the Lower Mississippi Valley

## 1. ANALYTICAL METHODS

### 1.1 Optically Stimulated Luminescence

The point bar sediments were dated using optically stimulated luminescence (OSL) due to the lack of material for radiocarbon dating and because of the proven success of OSL dating to similar fluvial deposits in the lower Mississippi River (Chamberlain and Wallinga, 2019; Holbrook et al., 2006; Rittenour et al., 2007; Shen et al., 2012). OSL provides an age estimate of the last exposure of mineral grains to sunlight or heat, which resets the luminescence signal (Huntley et al., 1985). Following burial, exposure to ionizing radiation from the surrounding sediments and cosmic rays leads to the accumulation of trapped charge (free electrons) in defects in the crystal-lattice structure. These trapped charges produce luminescence (photons of light) when stimulated by controlled light in the laboratory. The intensity of the luminescence

signal is related to the radioactivity of the depositional environment and duration of burial (i.e. the age of last exposure to light or heat) (Rhodes, 2011).

OSL dating can be challenging in fluvial environments. Specifically, river systems can have turbid water conditions, rapid transport times, and even sediment buffering from the floodplains which can be associated with partial bleaching (incomplete resetting) of the sediments (Rittenour, 2008; Wallinga, 2002). Deposits in these settings, however, can be accurately dated by selecting depositional facies which are most likely to have been reset by sunlight exposure (Brown, 2020; Fuchs and Owen, 2008; Summa-Nelson and Rittenour, 2012) or through use of age models (Galbraith and Roberts, 2012) and small aliquots of sediment (Duller, 2008; Olley et al., 1998).

Seven samples for OSL dating were collected from the abandoned point bar complex at False River, Louisiana using a Geoprobe push-driven coring rig with opaque plastic core liners. Samples were processed at the Luminescence Laboratory at Utah State University (USU) for OSL analysis. All samples were opened and processed under dim, amber safelight conditions (~590 nm). Sample processing for quartz OSL dating followed standard procedures involving wet sieving to 75–125 µm, 10% HCl and 5% H<sub>2</sub>O<sub>2</sub> treatments to remove carbonate and organic material, heavy mineral separation at 2.72 g/cm<sup>3</sup>, and acid treatments with 48% HF and 38% HCl and to isolate the quartz component of a narrow grain-size range,. The purity of the quartz samples was checked by measurement with infrared stimulation to detect the presence of feldspar. Luminescence measurements were performed on Risø TL/OSL Model DA-20 readers equipped with blue-green light emitting diodes (LED) (470±30 nm) and detection through 7.5-mm UV filters (U-340) (Bøtter-Jensen et al., 2003). Stimulation was conducted at 125 °C following 240 °C preheats (10 s) for regenerative and natural doses.

Samples were analyzed following the single-aliquot regenerative-dose (SAR) procedure (Murray and Wintle, 2003) on 1-mm aliquots of 75–125  $\mu\text{m}$  quartz sand (~70 grains per disk). The SAR sequence had five regenerative doses and included a repeated dose and zero-dose step (regenerative points at ~5, 10 and 15 Gy, 10 Gy test dose). Data quality criteria include the rejection of aliquots with IR signal response, recycling ratio of the repeat point  $>1.1$  and  $<0.9$ , and recuperation of the zero-dose step  $>1$  Gy. The equivalent dose ( $D_E$ ) was calculated using the Minimum Age Model (MAM, (Galbraith and Roberts, 2012) due to skew in the  $D_E$  data and expected partial bleaching in the sediments (Fig. S8). The OSL age is reported at  $1\sigma$  standard error and is calculated by dividing the  $D_E$  (in grays, Gy) by the environmental dose rate (Gy/kyr) that the sample has been exposed to during burial (Table 2 and S4).

Samples for dose rate determination we collected from sediments above and below each OSL sample interval of the cores. The sediments were homogenized and representative samples were analyzed for radioisotope concentration using ICP-MS and ICP-AES techniques (Table S4). These concentration values were converted to dose rate following the conversion factors of Guérin et al. (2011) and beta attenuation values of Brennan (2003). Sediments from within the OSL samples were dried to determine *in-situ* water content. Contribution of cosmic radiation to the dose rate was calculated using sample depth, elevation and latitude/longitude following Prescott and Hutton (1994). Total dose rates were calculated based on water content, radioisotope concentration, and cosmic contribution (Adamiec and Aitken, 1998; Aitken and Xie, 1990; Aitken, 1998).

## 1.2 Grain Size

A total of twenty-five samples from both the False River point bar and the modern river analyzed following the procedure of (Hulse and Bentley Sr, 2012). About 2 g of sample were placed in a 50 ml plastic centrifuge tube with 5.75 ml of NaPO<sub>3</sub> solution. Each tube was capped and vortexed to deflocculate clay-sized sediment and separate organic particles. The sample was poured through an 850-μm sieve to help remove large particles of organic matter. The glass tube was placed into a centrifuge to settle the sediment at the bottom of the vial. The vials were then run at ~25 RPM for 60 minutes and the supernatant was then removed. About 2 ml of NaPO<sub>3</sub> was then added to the centrifuged sample, as well as 5 ml of H<sub>2</sub>O<sub>2</sub>. Small amounts of acetone were sprayed in the vials to stabilize the reaction, following which the samples were placed in a hot bath set at 70°C over night. Once removed from the hot bath the supernatant was removed from the vials and the samples were transferred into plastic tubes with caps to be vortexed for analysis. The samples were then analyzed using a Beckman-Coulter (LS 13-320SW Laser Diffraction Particle Size Analyzer Single Wavelength) at Louisiana State University (LSU). Results are shown in Table 1 and S1.

## 1.3 Geochemical Analysis

X-Ray Fluorescence (XRF) analysis was completed at LSU. Loss on Ignition was determined by weighing out  $2.0000 \pm 0.02$  g of sample powder, igniting in a furnace at 950°C for two hours, and then re-weighing the sample powder. Glass fusion disks were then created by mixing  $0.600 \pm 0.006$  g of the ignited sample powder with  $6.000 \pm 0.06$  g of a 49.5% lithium metaborate + 49.5% lithium tetraborate + 0.5% lithium iodide flux in a platinum crucible and fusing the mixture at 1065°C using a Claisse LeNeo Fusion Fluxer. The resulting glass disks

were then loaded sequentially into the 10-position carousel of the PANalytical Epsilon3<sup>XLE</sup> energy-dispersive XRF spectrometer at the LSU Shared Instrumentation Facility. Each sample was run in triplicate under a series of varying conditions, which are ideal for different groups of elements of interest. The current for each condition is automatically set by the instrument to maximize the intensity of the elements of interest while reducing artifacts.

Quantitation of the analyses was performed based on a set of standards from the Geophysical Survey of Japan (JA-3 Andesite, JB-2 Basalt, JG-2 Granite, JLk-1 Lake Sediment, JLS-1 Limestone, JP-1 Peridotite, JR-1 Rhyolite) and the United States Geological Survey (AGV-1 Andesite, BIR-1 Iceland Basalt, SCo-1 Cody Shale, W-2 Diabase, G-2 Granite, GSP-2 Granodiorite, SGR-1 Green River Shale, QLO-1 Quartz Latite, RGM-1 Rhyolite, SDC-1 Mica Schist, STM-1 Syenite). The calibration curves were derived from the statistical means of ten repeat analyses of each standard. Three standards, USGS MAG-1 (Marine Sediment), GSJ JSd-1 (Stream Sediment), and GSJ JSI-1 (Slate) were analyzed in triplicate as unknowns at the beginning and end of each analytical session to check the accuracy of the calibration and to monitor for instrumental drift.

#### **1.4 Zircon U-Pb Dating**

Samples for DZ analysis were processed at GeoSep Services Inc in Moscow, Idaho by sieving, washing with water to remove lighter particles, separation in Lithium Metatungstate to remove particles with a specific gravity less than 2.95 g/cm<sup>3</sup>, removal of magnetic grains with a Frantz™ magnetic separator, separation in Di-iodomethane to remove particles with a specific gravity less than 3.33 g/cm<sup>3</sup> (GeoSepServices). Zircon separates were sprinkled in the center of

circular epoxy silicon molds that were placed into a vacuum chamber and degassed to release air from bubbles. The molds cured for 48 hours and were then polished.

A total of seven mounts were analyzed at the London Geochronology Centre (LGC) and two at Washington State University. At LGC U-Pb dating samples were analyzed by laser ablation (LA) ICP-MS using a New Wave 193 nm Excimer laser ablation system coupled to an Agilent 7900 quadrupole-based ICP-MS. The laser was set up to produce an energy density of ca 2.5 J/cm<sup>2</sup> at a repetition rate of 10 Hz. The time-resolved mass spectrometer data were processed using GLITTER 4.5 data reduction software. Data were filtered to exclude mixed ratios, non-zircons based on zirconium concentrations (>10 counts per second) and a  $-5/+15\%$  discordance threshold was applied. Repeated measurements of external zircon standard PLESOVIC (TIMS reference age 337.13 $\pm$ 0.37 Ma; (Sláma et al., 2008)) and NIST 612 silicate glass (Pearce et al., 1997) were used to correct for instrumental mass bias and depth-dependent inter-element fractionation of Pb, Th and U. 91500 (Wiedenbeck et al., 2004) and Temora (Black et al., 2003) zircon were used as secondary age standards. The  $^{206}\text{Pb}/^{238}\text{U}$  ratio was used to determine ages where <1000 Ma and the  $^{207}\text{Pb}/^{206}\text{Pb}$  ratio for older grains. IsoplotR software was used for data plotting (Vermeesch, 2018).

At the GeoAnalytical Laboratory at Washington State University isotopic analyses were performed with a New Wave UP-213 LA system in conjunction with a Agilent 7700x quadrupole LA-ICP-MS. For all analyses the beam diameter was 30  $\mu\text{m}$  and the frequency was set at 5 Hz, yielding ablation pits  $\sim$ 12–15  $\mu\text{m}$  deep. He and Ar gas were used to deliver the ablated material into the plasma source. Each analysis of 32 cycles took approximately 30 seconds to complete and consisted of a 6-second integration on peaks with the laser shutter

closed (for background measurements) followed by a 24-second integration with the shutter open and the laser ablating zircon material. Several zircon U-Pb age standards were used during analysis for calibration purposes. These included the 1099 0.6 Ma FC zircon (FC-1 of Paces and Miller, 1993) as the primary age standard. The secondary age standard was the 61.2 0.1 Ma Tardree Rhyolite zircon (David Chew, pers. comm.). Third-level age standards included the Fish Canyon Tuff with an age of  $28.20 \pm 0.1$  Ma (Lanphere and Baadsgaard, 2001), the Mount Dromedary Syenite with an age of  $99.1 \pm 0.1$  Ma (Renne et al., 1998), and the Temora2 diorite with an age of  $416.8 \pm 0.3$  Ma (Black et al., 2004). At the beginning of the LA-ICP-MS session, zircon standards (TR and FC1) were analyzed until fractionation was stable and the variance in the measured  $^{206}\text{Pb}/^{238}\text{U}$  and  $^{207}\text{Pb}/^{206}\text{Pb}$  ratios was at or near 1%.  $^{207}\text{Pb}/^{235}\text{Uc}$  ( $^{235}\text{Uc} = 137.88^{238}\text{U}$ ),  $^{206}\text{Pb}/^{238}\text{U}$ , and  $^{207}\text{Pb}/^{206}\text{Pb}$  ages were calculated for each data scan and checked for concordance; concordance here was defined as overlap of all three ages at the  $1\sigma$  level (the use of  $2\sigma$  level was found to skew the results to include scans with significant common Pb). If the number of concordant data scans for a spot was greater than zero, then either the  $^{206}\text{Pb}/^{238}\text{U}$  (for ages  $<1.0$  Ga) or  $^{207}\text{Pb}/^{206}\text{Pb}$  (for ages  $>1.0$  Ga) age was chosen as the preferred age. Common Pb was subtracted out using the Stacey (1975) common Pb model for Earth. Ages and common Pb ratio were determined iteratively using a pre-set, session-wide minimum common Pb age value. Results are provided in Table S1. Data for this paper are also available from Mendeley Data at <https://data.mendeley.com/datasets/trtnw8vx95/draft?a=4923e382-b53a-4f11-a36b-14e61ca09ac1>, and from the Geochron database at the University of Arizona (<http://geochron.org/>).

It is important to consider the different potential crystal domains analyzed in various DZ studies when comparing with published data. Studies targeting rims (for younger zircon growth

events) or cores (for inherited zircon ages) can produce different DZ U-Pb age distributions for the same sample and grains dated here were imaged in advance of analysis, with rim preferentially targeted.

## 2. REGIONAL GEOLOGICAL SUMMARY

DZ U-Pb dating only functions as an effective provenance proxy if the various source terrains of the river have contrasting DZ age spectra, which are a reflection of geological history of the crustal block. Here we briefly summarize the major tectonic units lying within the modern Mississippi catchment and note their defining characteristics that might be identified in the sediments sampled in the lower reaches.

The Superior Province (>2.5 Ga) is the largest Archean craton in North America. This stable crustal block is exposed across much of central Canada, as well as the northern border of the continental United States, excluding Alaska. This craton underwent a series of tectono-magmatic events which included growth, deformation, and accretion of both oceanic and continental crust (Percival et al., 2012). The Superior Province formed following collision of major tectonic blocks, specifically the Slave-Rae-Hearne cratons (Hoffman, 1989).

The Trans-Hudson Province (2.3–1.8 Ga) spans approximately 500 km wide and is bound by the Hearne-Wyoming and Superior cratons. These three cratons eventually formed the core of the North American continent, otherwise known as Laurentia (Hoffman, 1989). The Hearne-Wyoming and Superior cratons sutured together to form a network of Paleoproterozoic orogenic belts, which include margins of three supercontinents: Laurasia, Pangaea, and Kenorland (Stauffer, 2006).

The Yavapai/Mazatzal Province (1.8–1.6 Ga) represents two cycles of crustal development during the Early Proterozoic and these terrains underlie the southwestern and midcontinental regions of North America. The Yavapai crustal development cycle (1.79–1.69 Ga)(Holland et al., 2015) consolidated rocks during an episode of deformation, metamorphism, and plutonism, and spans from Arizona through Colorado into the northeast US (Fig. 3). The Mazatzal crustal development cycle (1.71–1.62 Ga)(Holland et al., 2020) includes volcanic rocks, arenites, and turbiditic sandstones, which experienced folding and thrusting, followed by plutonism (Hoffman, 1989). The Mazatzal Province stretches from northern Mexico into Canada.

The Granite-Rhyolite Province (1.48–1.34 Ga) affects basement terrains across the Midwest region, as well as extending east into New York state (Bickford and Van Schmus, 1985; Muehlberger et al., 1967). Felsic magmatic rocks are present throughout the midcontinental United States, but in the southwest region, this magmatism intruded the Yavapai/Mazatzal Province. The early magmatism represents anorogenic or A-type granites, which were emplaced during three separate magmatic events (Anderson, 1983). The tectonic setting of the magmatism is unclear in terms of its geochemistry (Barnes et al., 2002).

The Grenville Province (1.25–1.00 Ga) extends from northern parts of Mexico, into the northern Midwest and central Canada (Dalziel, 1991). Its tectonic history included early magmatism, metamorphism, and arc accretion against Laurentia (Karlstrom et al., 1999). Overall, this terrain is the product of multiple collisional events, which resulted in the formation of Rodinia (Dalziel, 1991; Moores, 1991).

The Peri-Gondwana Province (650–500 Ma), whose ages reflect the Pan-African Orogeny includes parts of the Appalachian Mountains, which were constructed from a series of

collisional events that accreted oceanic arcs and Gondwana-derived blocks to Laurentia. Also, the Peri-Gondwana Province includes the Suwannee Block, which accounts for the accreted basement Gondwanan terrain in Florida and Tennessee (Mueller et al., 1994).

Zircon ages in the Appalachian Mountains often reflect the imprint of the Taconic Orogeny (500–380 Ma) that affected eastern North America during the Ordovician-Devonian. Events that occurred in the Northern Appalachians include disconformities of carbonates, deformation of volcanic rocks, gravity slides from uplift, and widespread deformation. The southern portion of the Appalachians were also affected greatly by the Taconic Orogeny, but with greater influence from the later Alleghenian Orogeny (300–250 Ma)(Rodgers, 1971).

The Cordilleran Province (<250 Ma) stretches from southern California through the northwestern United States, through western Canada, southeast Alaska, and terminates at the Arctic coast. This terrain was altered through many active margin processes throughout the mid-Mesozoic through Eocene and was subsequently modified during the Cenozoic Basin and Range extension (Constenius, 1996; DeCelles, 2004). The Cordillera (with a few notable exceptions, e.g., the Cretaceous Boulder Batholith (Hamilton and Myers, 1974)) largely lie outside the catchment of the Mississippi, but earlier work indicates that common Cordilleran-aged zircons are found within the Sevier (Rocky Mountain) foreland basin from which they have been reworked following uplift related to the Laramide Orogeny (Balgord et al., 2021; Laskowski et al., 2013).

### 3. ZIRCON AGE COMPILATION

In order to determine the possible source of sediment to the lower reaches we have compiled existing bedrock zircon ages that can be compared to determine possible links.

Yavapai-Mazatal data are from Finzel (2014), Dickinson and Gehrels (2009), Van Schmus et al. (2007), Gehrels and Pecha (2014) and Gehrels et al. (2011); Peri-Gondwana data are from Weislogel et al. (2015), Macdonald et al. (2014) and Fyffe et al. (2009); Grenville data are from Spencer et al. (2014), Fisher et al. (2010), Macdonald et al. (2014) and Howard et al. (2015); Appalachian data are from Merschat et al. (2010), Becker et al. (2005) and Park et al. (2010). Trans-Hudson data are from Sun et al. (1996), Orrell et al. (1999), Skipton et al. (2016), Henrique-Pinto et al. (2017). Rocky Mountain foreland basin data are from Laskowski et al. (2013), Finzel (2017) and Balgord et al. (2021). Cordillera data are from Wright and Fahan (1988), Hurlow and Nelson (1993), Sauer et al. (2017), and DeGraaff-Surpless et al. (2019; 2003). Superior Province data are from Moser and Heaman (1997), Heaman (1997), Davis et al. (2005), Frieman et al. (2017) and Cleven et al. (2020). Granite-Rhyolite data are from Thomas et al. (2012), Freiburg et al. (2020), Van Schmus et al. (2007), Bickford et al. (2015), Dewane and Van Schmus (2007) and Barnes et al. (2002).

#### **4. STATISTICAL TESTING OF ZIRCON U-PB SPECTRA**

In addition to the MDS plot presented in the main text we can further objectively compare our sediments with modern tributaries and potential source terrains using a statistical test that compares the DZ age spectra using a Kuiper test (Kuiper, 1960) and the *DZStats* program of Saylor and Sundell (2016). We use the results of this test to generate a dissimilarity matrix in which similarities and differences are highlighted graphically and represented by warm and cool colors respectively (Fig.S7A). It is apparent that sediments in the modern lower reaches, those in the False River Point Bar and the LGM sediments are generally quite similar to one another, with a few notable exceptions.

When we compare these sediment samples with their major tributaries, we see that there is a general similarity in DZ U-Pb age distributions with the Red, Arkansas, Missouri and Upper Mississippi, but less so with the Ohio River (Fig. S7A). It is noteworthy that different sediments have different degrees of similarity with the various major tributaries, suggesting variable fluxes from each of these over relatively short time periods (annual or even shorter). Compared to the major source terrains we note that the Rocky Mountain foreland basin is uniformly the most similar to any of the recent sediments, as well as several of the western tributaries. It is apparent that the Appalachians, Superior Province, Trans-Hudson, and Cordilleran source terrains are the least similar to the river sediments. There is some association between the Mississippi sediments and the Grenville, Yavapai/Mazatal and Peri-Gondwana sources.

We constructed a separate colored dissimilarity matrix diagram with only the sediments in order to highlight differences between them that are minimized when we compare with the various source terrains and the tributaries (Fig. S7B). Sample LA1701 is somewhat different from many of the other sediments, while sediment W11-2 from the point bar stands out as being the most anomalous of any of the Holocene sediments. This shows that the river has not been entirely stable over historical times and even varies between years in the more recent past.

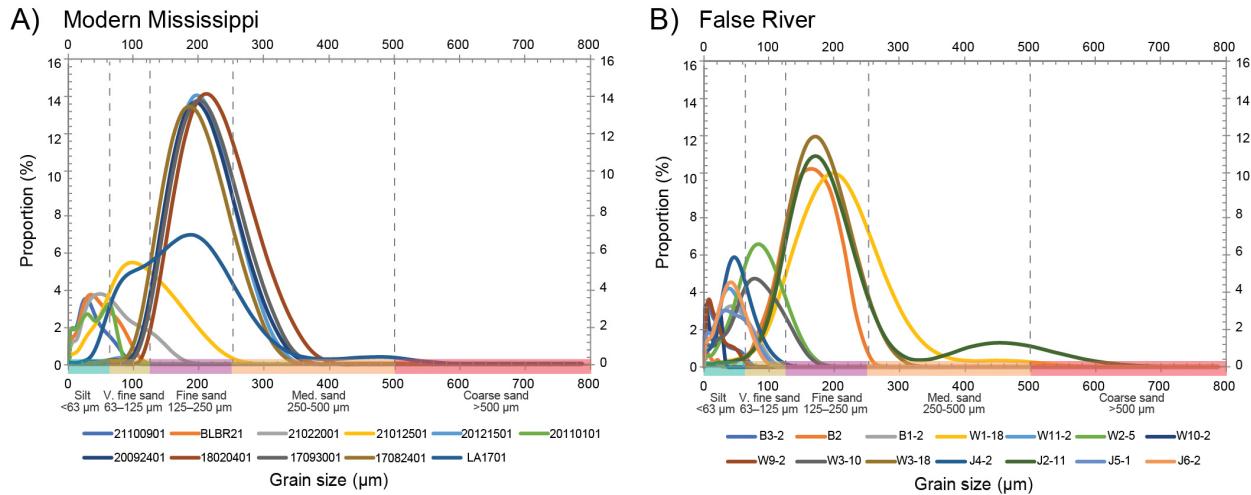

Figure S1. Grain size spectra for the sample as considered within the study showing the variability between A) the modern river and B) Holocene-historical samples. All samples are classified as dominantly silt to fine sand.

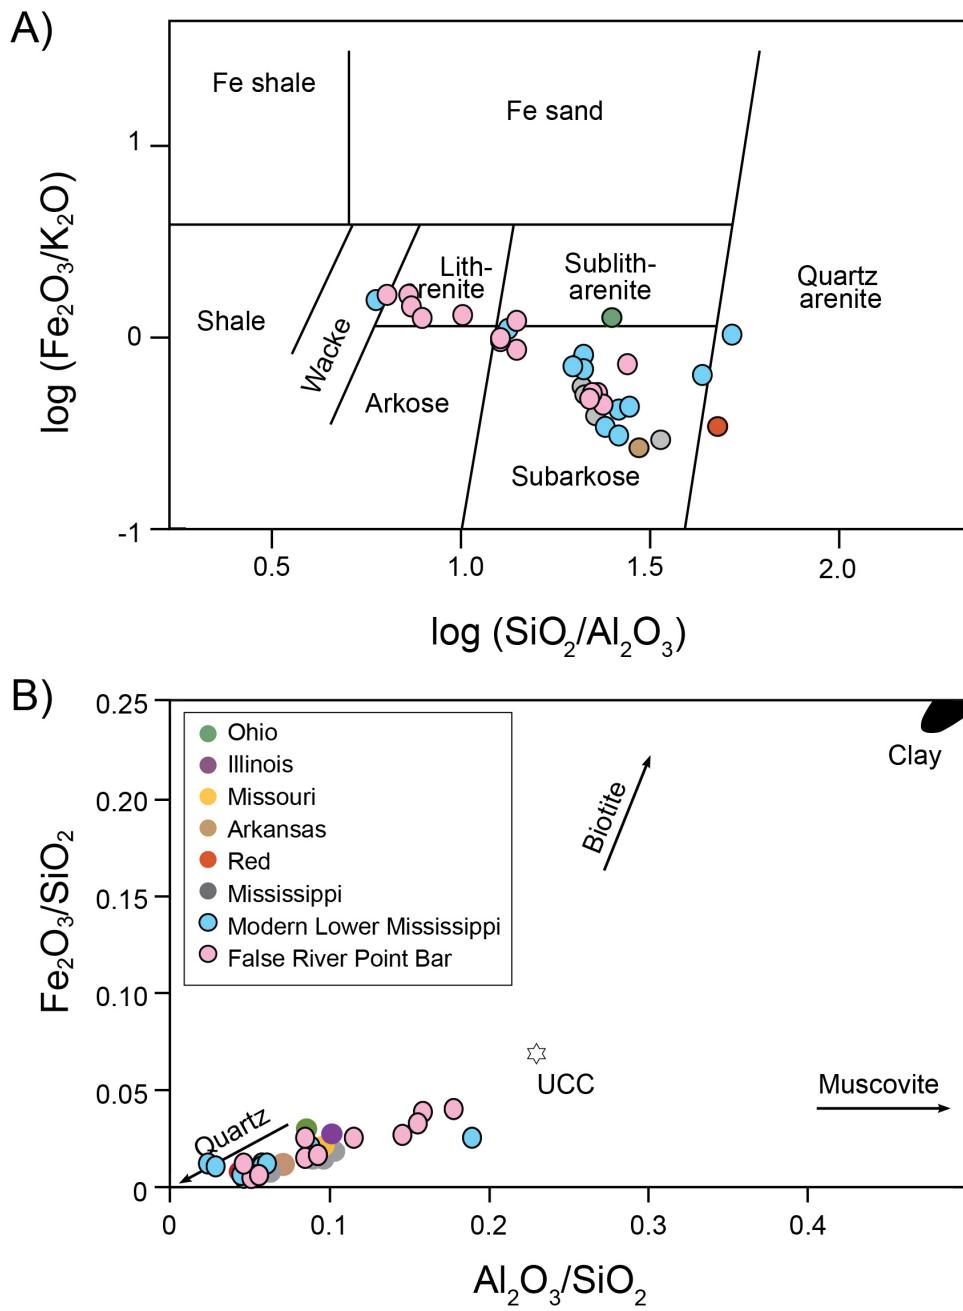

Figure S2. A) Geochemical classification of sediments from this study following the scheme of Herron (1988). B) Plot of  $\text{Al}_2\text{O}_3/\text{SiO}_2$  versus  $\text{Fe}_2\text{O}_3/\text{SiO}_2$  for sediments from the Mississippi River after Singh et al. (2005). Lower ratios indicate an increase of the quartz proportion and a depletion of phyllosilicates. The linear trend corresponds to mineralogical sorting of these sediments during fluvial transport. The star corresponds to average Upper Continental Crust (UCC)(Taylor and McLennan, 1995). Modern tributary data from Gregory et al. (2022).

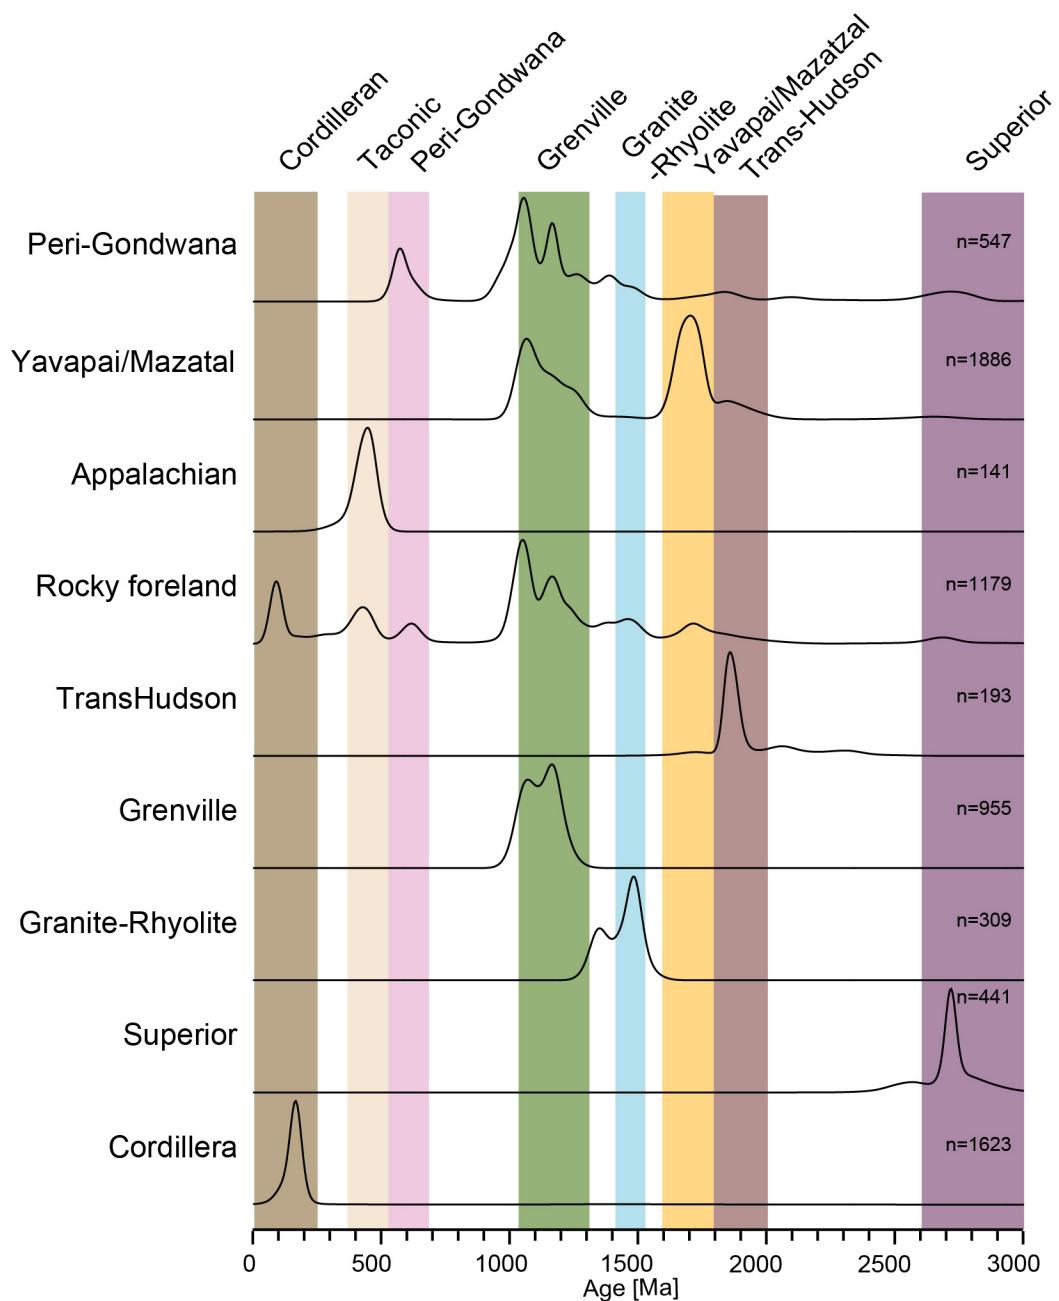

Figure S3. Kernel density estimate (KDE) diagrams showing the age distribution of the major basement tectonic blocks of North America that may be supplying sediment to the Mississippi River. Band width 15 m.y. Data are compiled from the literature and summarized in the online data supplement.

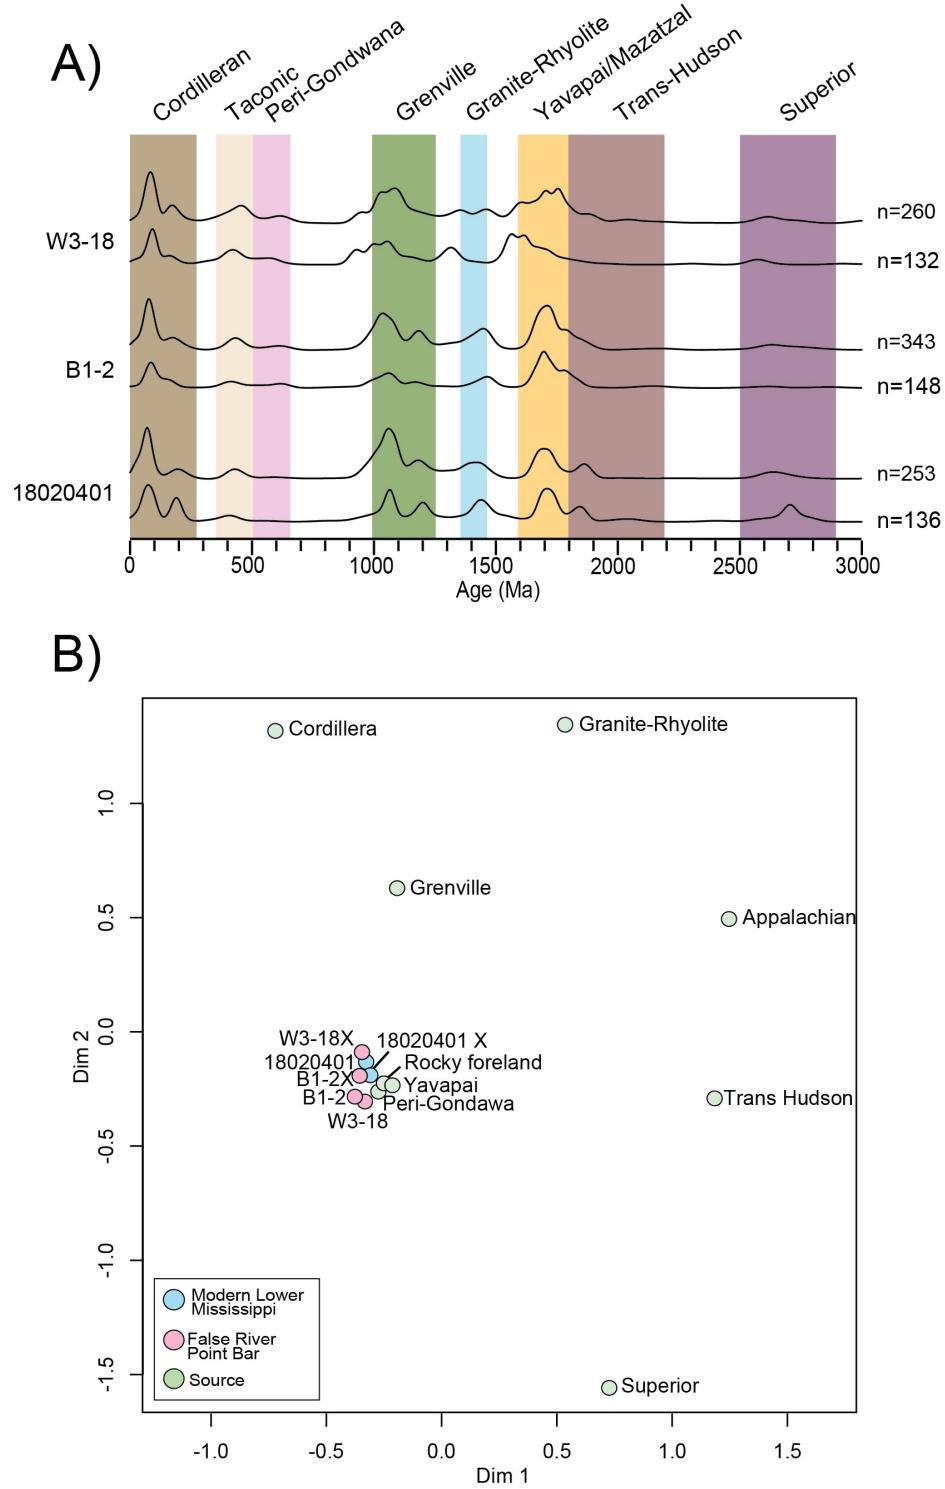

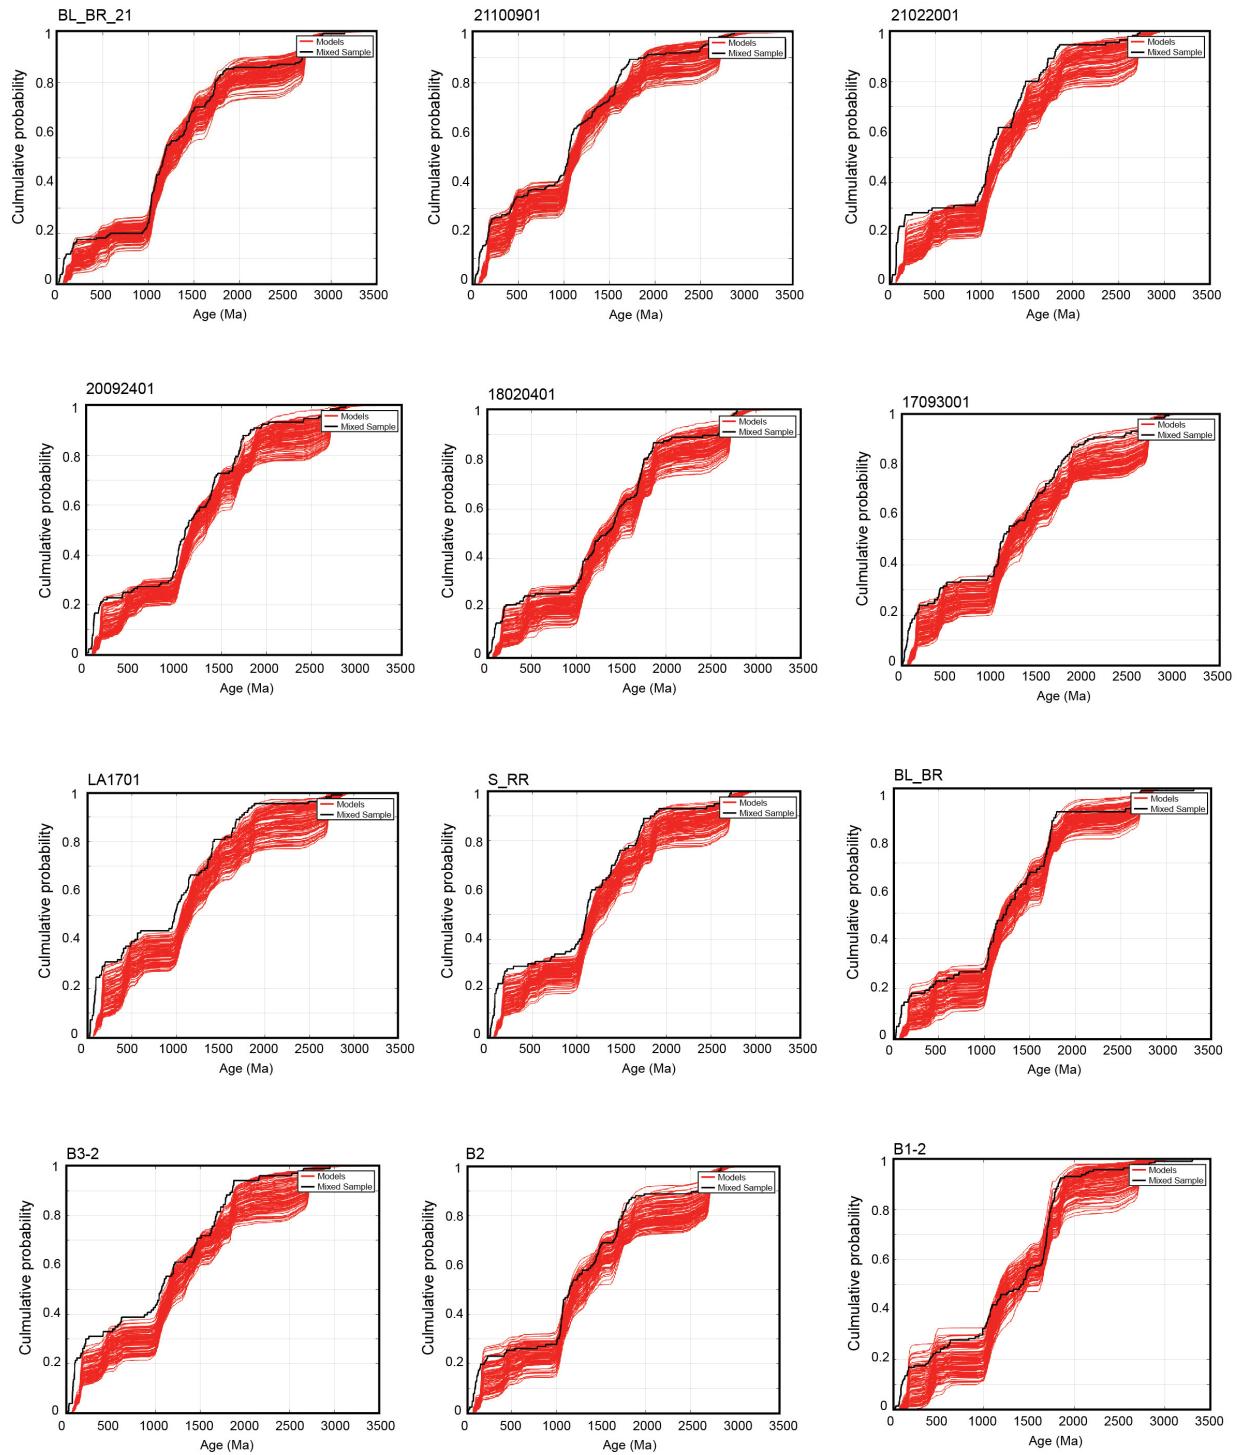

Figure S4. A) KDE plots comparing three samples that were analyzed first with a moderate number of grains and them with an expanded number in order to understand the impact of large sample size on the result. B) Multidimensional Scalar Diagram (MDS) comparing the small and large sediment samples with potential source regions. The analysis demonstrates that increasing the sample size has only a moderate impact on the final result.

### Basement end members, Kuiper V Statistics

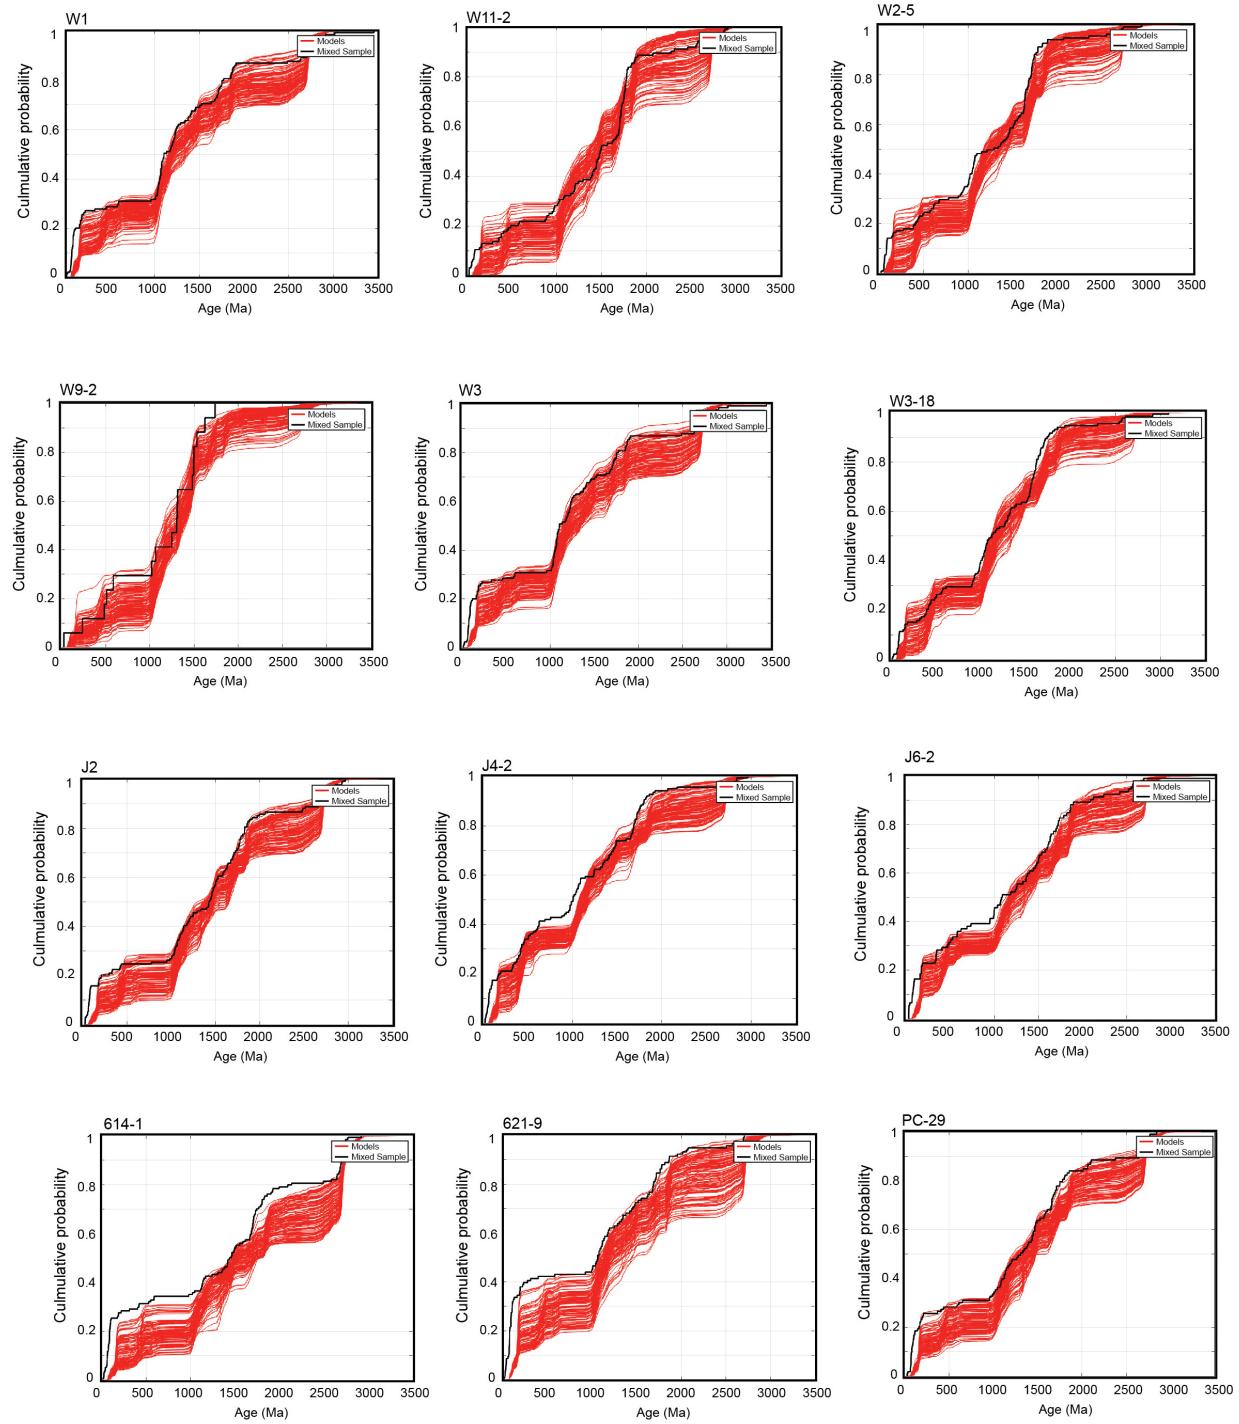

Figure S5. Figures showing cumulative frequency diagrams for each of the sediment samples considered here with the black line showing the observed spectrum and the colored lines showing the top 1% of models for each sample based on the stated statistical method employed. When the models largely overlap with the observed spectrum the preferred model can be considered statistically robust.

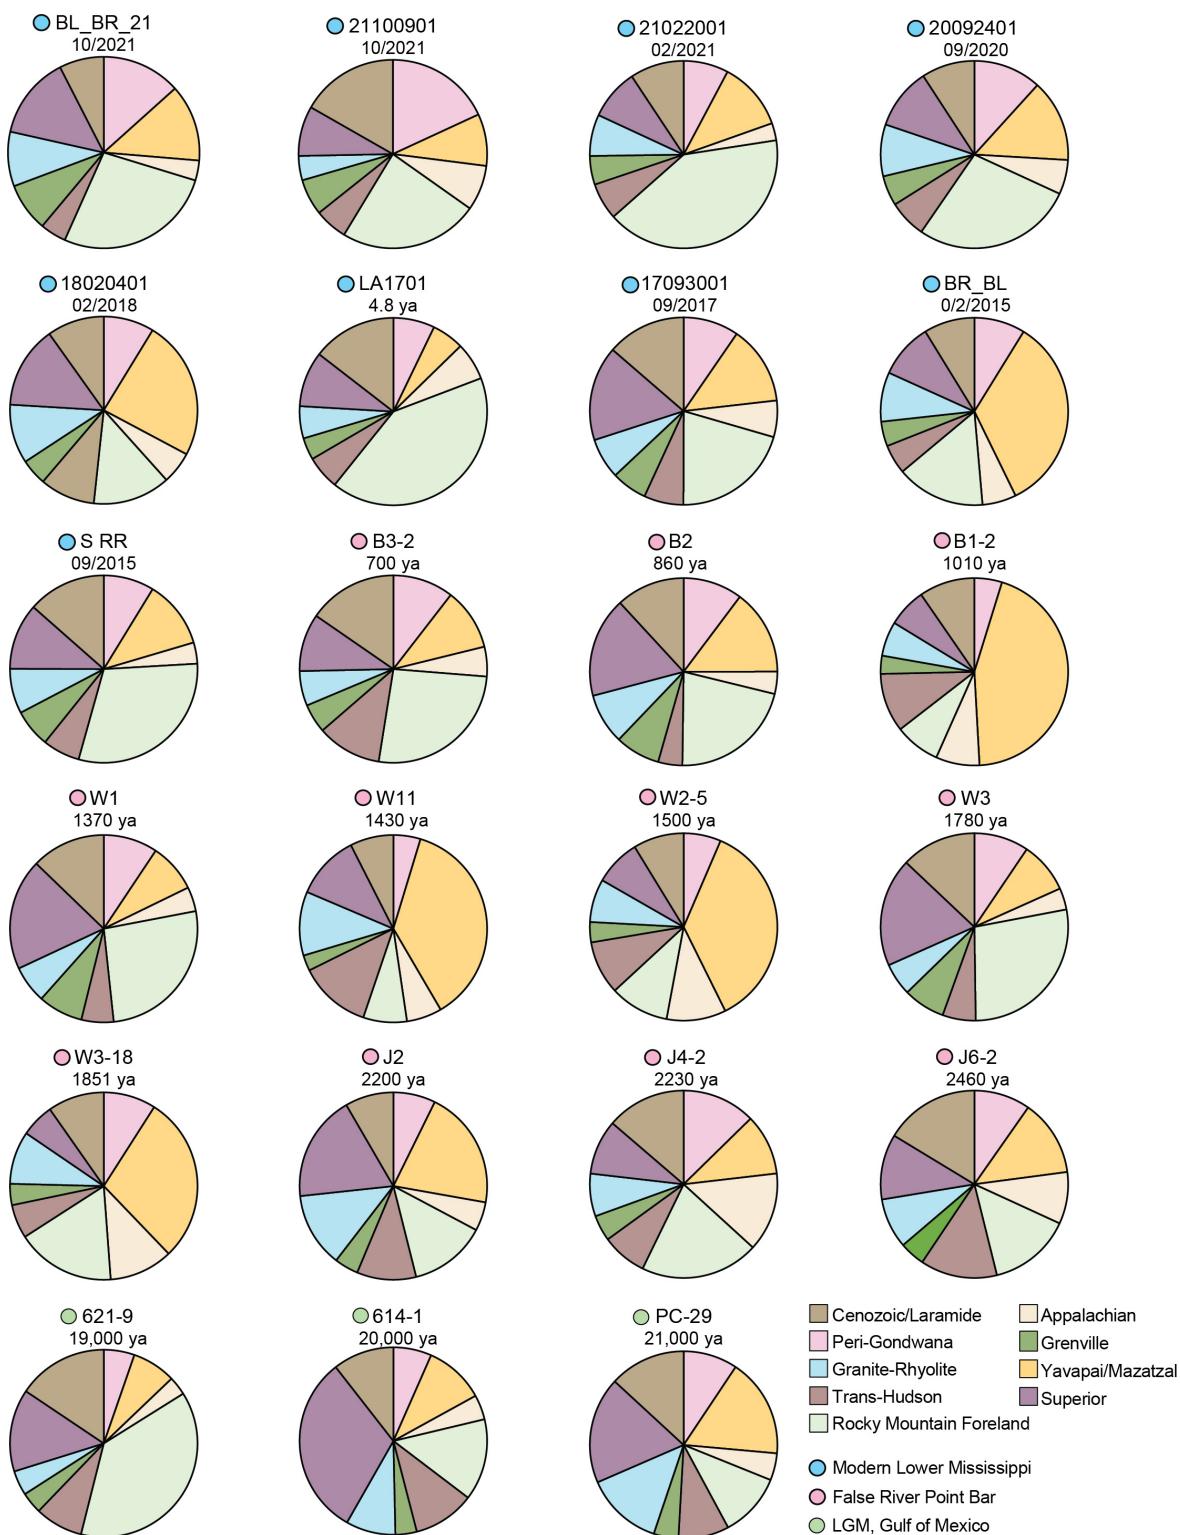

Figure S6. Estimated contributions from the major continental source terrains for each sample as calculated from the DZMix software of Sundell and Saylor (2017) using the Kuiper statistical test to estimate the contributions.

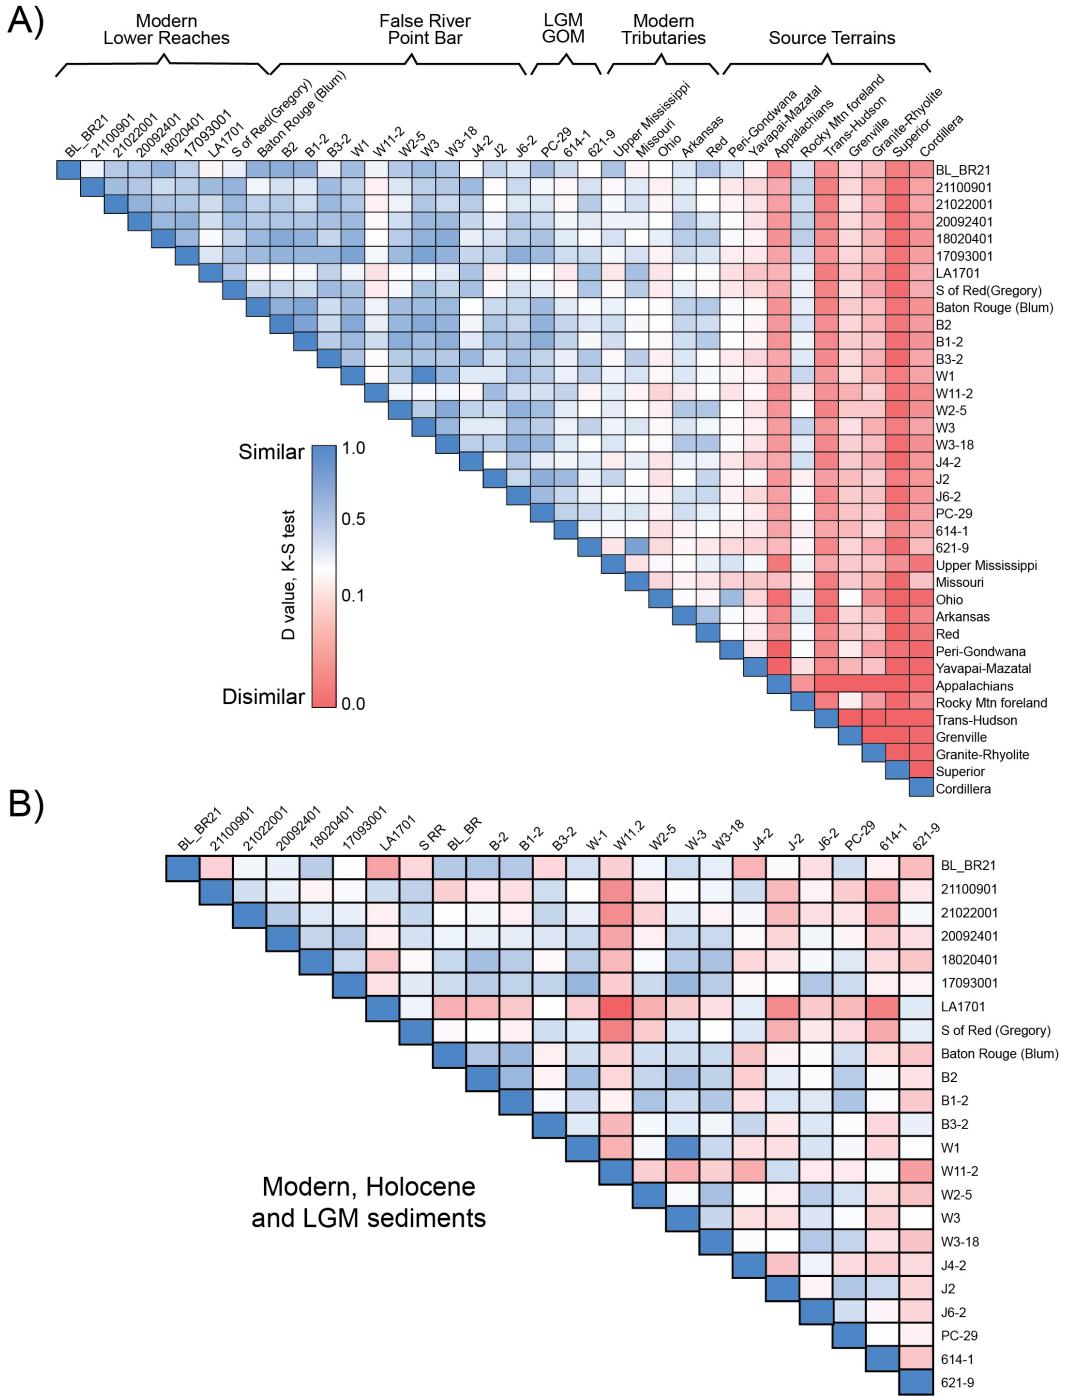

Figure S7. A) A dissimilarity matrix comparison of the zircon age spectra for the different detrital sediment samples compared with LGM sediments from the Gulf of Mexico (Fildani et al., 2016), modern major tributaries from Gregory et al. (2022) and basement sources compiled from the various terrains for the source regions to the Mississippi River. Note the dissimilarity of most of the sediments with the Appalachian, Trans-Hudson and Superior provinces, but the strong similarity of many samples with the Rocky Mountain foreland. B) A dissimilarity matrix of only the LGM and younger sediments emphasizing differences between the lower river in recent geological time.
